

LF400A/LF400 **Fast-Settling JFET-Input Operational Amplifier**

General Description

The LF400 is a fast-settling (under 400 ns to 0.01% for a 10V output step) Bi-FET operational amplifier. Features include 16 MHz bandwidth, 60V/ μ s inverting slew rate, low input offset voltage (0.5 mV for the LF400A at 25°C), and adjustable output current limit, enabling the amplifier to drive 600 Ω loads.

Applications

- DAC output amplifiers
- High speed ramp generators
- Fast buffers
- Sample-and-holds
- Fast integrators
- Piezoelectric transducer signal conditioners

Absolute Maximum Ratings (Notes 1 & 2)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage	± 18V
Differential Input Voltage	± 32V
Input Voltage Range (Note 3)	± 16V
Output Short Circuit Duration (Pin 6)	Continuous
Power Dissipation (Note 4) H package	500 mW
Junction Temperature (T _{JMAX})	150°C
Storage Temperature	− 65°C to + 150°C
Lead Temperature (Soldering, 10 sec.)	+ 300°C
ESD Susceptibility (Note 9)	800V

Operating Ratings (Notes 1 & 2)

Temperature Range	T _{MIN} ≤ T _A ≤ T _{MAX}
LF400AMH, LF400MH	− 55°C ≤ T _A ≤ + 125°C
LF400ACH, LF400CH	0°C ≤ T _A ≤ + 70°C
Positive Supply Voltage	+ 10V to + 16V
Negative Supply Voltage	− 10V to − 16V

AC Electrical Characteristics (LF400ACH, LF400CH)

The following specifications apply for V⁺ = +15V and V[−] = −15V unless otherwise specified.

Tested Limits in Boldface apply for T_J = 25°C to 95°C. Design Limits in Boldface apply for T_A = T_{MIN} to T_{MAX}; other Design Limits are for T_A = 25°C; all other limits for T_J = 25°C.

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications do not apply when operating the device beyond its specified operating conditions.

Note 2: All voltages are with respect to ground.

Note 3: Unless otherwise specified, the Absolute Minimum Input Voltage is equal to the negative power supply voltage.

Note 4: The maximum power dissipation must be derated at elevated temperatures as is dictated by T_{JMAX} , θ_{JA} , and the ambient temperature T_A . θ_{JA} for the LF400H is $150^\circ C/W$ in free air, so a heat sink will generally be required when T_A is greater than about $70^\circ C$. θ_{JC} for the LF400H is $17^\circ C/W$, which dictates the use of a heat sink with θ_{CA} less than about $35^\circ C/W$ when $T_A = +125^\circ C$.

Note 5: The input bias currents are junction leakage currents which approximately double for every $10^\circ C$ increase in the junction temperature T_J . Due to limited production test time, input bias currents are measured at $T_J = 25^\circ C$. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation P_D . Use of a heat sink is recommended when input bias current must be minimized.

Note 6: Typicals represent the most likely parametric norm.

Note 7: Guaranteed to National's AOQL (Average Outgoing Quality Level).

Note 8: Guaranteed, but not 100% production tested. These limits are not used to calculate outgoing quality levels.

Note 9: Human body model, 100 pF discharged through a 1500Ω resistor.

Application Hints

The LF400 is a high-speed, low input bias current Bi-FET operational amplifier capable of settling to 0.01% of a 10V output swing in less than 400 ns. The rugged JFET inputs allow differential input voltages as high as 32V without a large increase in input current. However, the inputs should never be driven to voltages lower than the negative supply, as this can result in input currents large enough to damage the device. To prevent this from occurring when power is first applied, always turn the positive and negative power supplies on simultaneously, or turn the negative supply on first.

Exceeding the common-mode input range will not damage the device as long as the Absolute Maximum Ratings are not violated, but it will result in a high output voltage. Latching will not occur, however, and when the offending signal is removed the LF400 will recover quickly.

The nominal power supply voltage is $\pm 15\text{V}$, but the LF400 will operate satisfactorily from $\pm 10\text{V}$ to $\pm 16\text{V}$. The LF400 is functional down to $\pm 5\text{V}$, but performance will be degraded. (See Typical Performance curves.)

Settling Time Considerations

The settling performance of any high-speed operational amplifier is highly dependent on the external components and circuit board layout. Capacitance between the amplifier summing junction and ground affects the closed-loop transfer function and should be minimized. The compensation capacitor C_C between the output and the inverting input should be carefully chosen to counteract the effect of the

input capacitance. Since input capacitance is made up of several stray capacitances that are difficult to predict, the compensation capacitor will generally have to be determined empirically for best settling time. A good starting point is around 10 pF for $A_V = -1$.

Settling time may be verified using a circuit similar to the one in Figure 1. The LF400 is connected for inverting operation, and the output voltage is summed with the input voltage step. When the LF400's output voltage is equal to the input voltage, the voltage on the gate of Q1 will be zero. Any voltage appearing at this point will represent an error. The FET source follower output is observed on an oscilloscope, and the settling time is equal to the time required for the error signal displayed on the oscilloscope to decay to less than one-half the necessary accuracy (see oscilloscope photos of "Settling Time—Positive Output Swing" and "Settling Time—Negative Output Swing"). For a 10V input signal, settling time to 0.01% (1 mV) will occur when the displayed error is less than $\frac{1}{2}$ mV. Since settling time is strongly dependent on slew rate, settling will be faster for smaller signal swings. The LF400's inverting slew rate is faster than its non-inverting slew rate, so settling will be faster for inverting applications, as well.

It is important to note that the oscilloscope input amplifier will be overdriven during a settling time measurement, so the oscilloscope must be capable of recovering from overdrive very quickly. Very few oscilloscopes are suitable for this sort of measurement. The signal generator used for set-

Application Hints (Continued)

FIGURE 1. Simplified Settling Time Test Circuit (see Text)

TL/H/9414-21

ling time testing must be able to drive 50Ω with a very clean $\pm 5V$ square wave. For more information on measuring settling time, see Application Note AN-428.

Output Compensation

When operating at very low temperatures, a compensation network should be added to the LF400's output. The 100Ω/22 pF network shown on the first page of this data sheet should be used when the junction temperature might reach 25°C (roughly 0°C ambient when the LF400 is "warmed up"). In applications where the device will be operating with a junction temperature near 0°C, the output RLC network in Figure 1 should be used. This network will provide a small (about 20 ns) improvement in settling time at higher temperatures, as well.

Supply Bypassing

Power supply bypassing is extremely important for good high-speed performance. Ideally, multiple bypass capacitors as in Figure 2 should be used. A 10 μF tantalum, a 2.2 μF ceramic, and a 0.47 μF ceramic work well. All bypass capacitor leads should be very short. For best results, the ground leads of the capacitors should be separated to reduce the inductance to ground. A ground plane layout approach will give the best results. For simplicity, bypass capacitors have been omitted from some of the schematics in this data sheet, but they should always be used.

TL/H/9414-22

FIGURE 2. Power Supply Bypassing (see Text)

Output Drive and Current Limit

The LF400 can drive heavier resistive loads than most operational amplifiers. The output at pin 6 is internally current-limited when the voltage drop across the 25Ω output resistor reaches about 0.55V ($I_{OUT} = 22$ mA). When more output current is needed, pin 8 provides a means of increasing the maximum output current up to about 100 mA. A resistor may be connected from pin 8 to pin 6, paralleling the internal sense resistor and increasing the current limit threshold (Figure 3). Pins 6 and 8 may be shorted together to completely bypass the current limiting circuit. To avoid damaging the LF400, observe the power dissipation limitations mentioned in the Absolute Maximum Ratings and in Note 4.

The effective load impedance (including feedback resistance) should be kept above 500Ω for fastest settling. Load capacitance should also be minimized if good settling time is to be optimized. Large feedback resistors will make the circuit more susceptible to stray capacitance, so in high-speed applications keep the feedback resistors in the 1 kΩ to 2 kΩ range wherever practical. Avoid the use of inductive feedback resistors (some wirewounds for example) as these will degrade settling time.

TL/H/9414-23

FIGURE 3. Increasing the current limit using pin 8. Current limit is now determined by R_X in parallel with the internal 25Ω sense resistor.

V_{OS} Adjustment

Offset voltage can be nulled using a 27k resistor and a 10k potentiometer connected to pins 1 and 5 as shown in Figure 4a. Bypassing the V_{OS} adjust pins with 0.1 μF capacitors will help to avoid noise pickup. When not used for offset adjustment, pins 1 and 5 can often be left open, but to minimize the possibility of noise pickup the unused V_{OS} trim pins should be connected to ground or V^- .

Application Hints (Continued)

TL/H/9414-24

FIGURE 4a. V_{0s} Adjust Circuit

TL/H/9414-25

FIGURE 4b. Automatic Offset Adjustment Using LMC669

In very critical applications where a manual adjustment is impractical, the LMC669 Auto Zero circuit may be used to reduce the effective input offset voltage to around $5\mu V$ as in Figure 4b. The LF400 will perform better than slower amplifiers in an auto zero loop, because its fast settling capability keeps its summing node voltage more stable. Therefore, the LMC669 is able to more accurately sample the summing node voltage before making an offset correction.

Input Bias Current

The JFET input stage of the LF400 ensures low input bias current (200 pA maximum) when the die is at room temperature, but this current approximately doubles for every $10^\circ C$ increase in temperature. In applications that demand the lowest possible input bias current, a heat sink should be used with the LF400. "Press on" heat sinks from manufacturers such as Thermalloy and AAVID can reduce junction temperature by roughly $10^\circ C$ to $40^\circ C$.

Typical Applications

High-Speed DAC with Voltage Output
