

Dual Phase, D-CAP+™, Eco-mode™ Step-Down Controller with 8-Bit DAC

Check for Samples: TPS53624

FEATURES

- Selectable Dual-or Single-Phase
- Minimum External Parts Count
- 8-Bit DAC Supports Wide Range of Applications
- Optimized Efficiency at Light and Heavy Loads
- Patented Output Overshoot Reduction (OSR)
 Reduces Output Capacitance
- Accurate, Adjustable Voltage Positioning
- Selectable 200, 300, 400 and 500 kHz Frequency
- Pat. Pending AutoBalance Phase Balancing
- Selectable 8-Level Current Limit
- 3-V to 28-V Conversion Voltage Range
- Fast MOSFET Driver with Integrated Boost Diode
- Integrated Overvoltage Protection (OVP)
- Small 6 x 6, 40-Pin QFN PowerPAD™ Package

APPLICATIONS

 High-Current, Low-Voltage ASIC or Microprocessor Core Regulator

DESCRIPTION

The TPS53624 is a dual-phase step down controller with integrated gate drivers. The PCNT pin enables operation in dual or single-phase mode to optimize efficiency depending on the load requirements. Advanced control features such as D-CAP+™ architecture and OSR provides fast transient response with low output capacitance. The DAC supports VID-on-the-fly to optimize the output voltage to the operating state of the system to reduce quiescent power. The auto-skip feature of the TPS53624 optimizes light-load efficiency in single phase operation. System management features include adjustable thermal monitor input and output (THRM, THAL), output current monitoring (IMON), and complimentary power good signals (PG and PGD). Adjustable control of the output voltage slew rate and voltage positioning are provided. In addition, the TPS53624 includes two high-current FET gate drivers to drive high and low side N-channel FETs with exceptionally high speed and low switching loss. All logic input and output pins have flexible LV input and output thresholds that enable interface with logic voltages from 1 V to 3.6 V.

The TPS53624 is packaged in a space saving, thermally enhanced, RoHS compliant 40-pin QFN and is rated to operate from -10°C to 105°C.

ORDERING INFORMATION(1)

T _A	PACKAGE	DEVICE NUMBER	PINS	OUTPUT SUPPLY	MINIMUM QUANTITY
10°C to 105°C	Plantin Ound Flat Book (OFN)	TPS53624RHAT	40	Tone and real	250
–10°C to 105°C	Plastic Quad Flat Pack (QFN)	TPS53624RHAR	40	Tape-and-reel	2500

For the most current package and ordering information, see the packaging information at the end of this document, or see the TI website
at www.ti.com.

M

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

ABSOLUTE MAXIMUM RATINGS

Over operating free-air temperature range (unless otherwise noted, all voltages are with respect to GND.) (1)

		VAI	VALUE		
		MIN	MAX	UNIT	
	VBST1, VBST2	-0.3	36		
(2)	VBST1to LL1. VBST2 to LL2	-0.3	6		
Input voltage range (2)	CSP1, CSN1, CSP2, CSN2, MODE, OSRSEL, PCNT, SLEW, THRM, TRIPSEL, TONSEL, V5FILT, V5IN, VID0, VID1, VID2, VID3, VID4, VID5, VID6, VID7, VFB, EN, THAL	-0.3	6	V

Storage junction temperature	e, T _{stg}	- 55	150		

⁽¹⁾ Stresses beyond those listed under "absolute maximum ratings" may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under "recommended operating conditions" is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

THERMAL INFORMATION

	THERMAL METRIC ⁽¹⁾	RHA (40 PIN)	UNITS
θ_{JA}	Junction-to-ambient thermal resistance	32	
θ_{JB}	Junction-to-board thermal resistance	10	°C/W

DEVICE INFORMATION

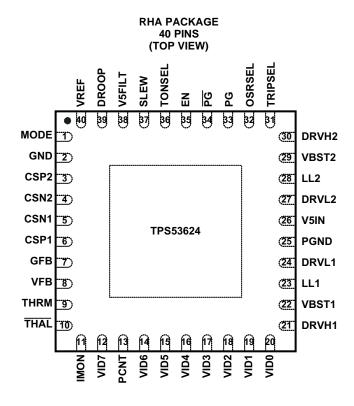

Table 1. PIN FUNCTIONS

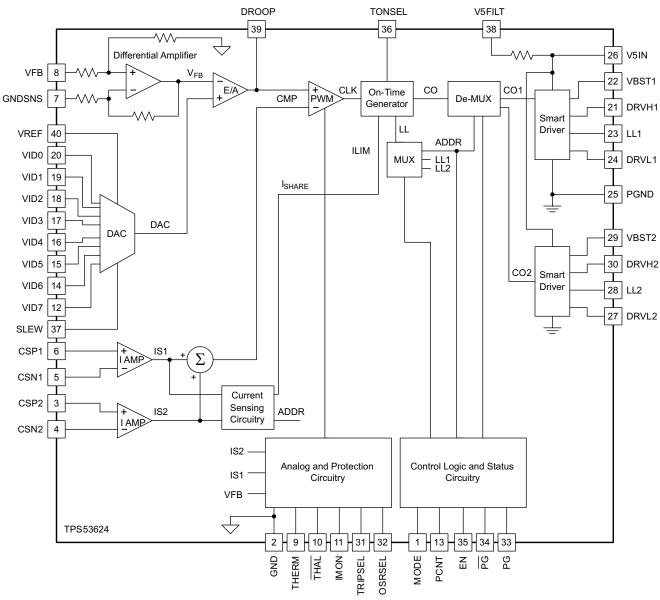

TERMI	NAL		
NAME	NO.	1/0	DESCRIPTION
CSP1	6	_	Positive current sense inputs. Connect to the most positive node of current sense resistor or inductor DCR
CSP2	3	Ι	sense R-C network.
CSN1	5	_	Negative current sense inputs. Connect to the most negative node of current sense resistor or inductor DCR
CSN2	4	I	sense RC network.
DROOP	39	0	Output of g_M error amplifier. A resistor to VREF sets the droop gain. A capacitor to VREF helps shape the transient response.
DRVH1	21	0	Lligh side Nighensel MOSEET gate drive outputs
DRVH2	30	0	High-side N-channel MOSFET gate drive outputs.
DRVL1	24	0	Symphysical N. shannel MOSEET gate drive systems
DRVL2	27	0	Synchronous N-channel MOSFET gate drive outputs.
EN	35	I	Controller enable. 3.3-V I/O level; 100-ns de-bounce. Logic high 3.3-V enables the controller. Logic low stops the controller.
GND	2	-	Return for analog circuits.
GFB	7	I	Voltage sense return tied directly to GND of the microprocessor. Tie to GND with a $100-\Omega$ resistor to close feedback when the microprocessor is not in the socket.
IMON	11	0	Current monitor output. $V_{IMON} = \Sigma V_{ISENSE} \times K \times R_{IMON}$. Reference R_{IMON} to GNDSNS. Voltage is clamped at 1.1-V maximum.
LL1	23	I/O	Historia National MOOFFT and alice as two Mary inset for a death and a finite a
LL2	28	I/O	High-side N-channel MOSFET gate drive return. Also, input for adaptive gate drive timing.
MODE	1		Tie to GND to select CPU mode.
OSRSEL	32	0	Overshoot reduction (OSR) setting. The OSR threshold can be selected or OSR can be disabled.
PG	34	0	Negative active power good output; Open drain. Transitions low of approximately 50 ms after VOUT reaches the VID level. Leave open if unused.

Table 1. PIN FUNCTIONS (continued)

TERMIN	AL		DECODIFICAL			
NAME	NO.	I/O	DESCRIPTION			
PGND	25		Synchronous N-channel MOSFET gate drive return.			
PG	33	0	Power good output; Open-drain. 6ms delay from voltage reaching the power good threshold. Leave open if unused			
PCNT	13	ı	Single or dual phase control. 1-V I/O level. A low is single phase mode.			
SLEW	37	I	Precision current set-point for slew rate control. Tie the R_{SLEW} resistor to GND for the low OCP range; tie R_{SLEW} to VREF for the high OCP range.			
THAL	10	0	Thermal flag open drain output - active low. Fall time < 100ns with 56Ω pull-up to 1V. 1ms de-glitch filter.			
THRM	9	I/O	Thermal sensor input. An internal, 60-µA current source flows into an NTC thermistor connected to GND. The voltage threshold is 0.75 V. Also is a <i>faults off</i> input, (THERM = V5FILT) for debug mode.			
TONSEL	36	ı	On-time selection pin. The operating frequency can be set between 200 kHz and 500 kHz in 100 kHz steps. Frequency can be changed during operation.			
TRIPSEL	31	ı	Overcurrent protection (OCP) setting. TRIPSEL is set with the R _{SLEW} connection. The valley current limit at the CS inputs can be selected in a range from approximately 10 mV to approximately 50 mV.			
VBST1	22	I	Lligh side N shannel MOSEET heatstrop voltage innuite			
VBST2	29	_	High-side N-channel MOSFET bootstrap voltage inputs.			
VID0	20

DETAILED DESCRIPTION

FUNCTIONAL OVERVIEW

The TPS53624 is a D-CAP+™ mode adaptive on-time converter. The output voltage is set using a DAC that outputs a reference in accordance with the 8-bit VID code defined in Table 5. VID-on-the-fly transitions are supported with the slew rate controlled by a single resistor on the SLEW pin. Two powerful integrated drivers support output currents in excess of 50 A. The converter enters single phase mode under PCNT control to optimize light-load efficiency. Four switching frequency selections are provided in 100-kHz increments from 200 kHz to 500 kHz per phase to enable optimization of the power chain for the cost, size and efficiency requirements of the design. (See Table 3)

•	•
TONSEL VOLTAGE (V _{TONSEL}) (V)	FREQUENCY (kHz)
GND (0)	200
VREF (1.7)	300
3.3	400
5	500

Table 3. Frequency Selection Table

In adaptive on-time converters, the controller varies the on-time as a function of input and output voltage to maintain a nearly constant frequency during steady-state conditions. In conventional voltage-mode constant on-time converters, each cycle begins when the output voltage crosses to a fixed reference level. However, in the TPS53624, the cycle begins when the current feedback reaches an error voltage level which is the amplified difference between the DAC voltage and the feedback voltage.

This approach has two advantages:

- 1. The amplifier DC gain sets an accurate linear load-line; this is required for CPU core applications.
- 2. The error voltage input to the PWM comparator is filtered to improve the noise performance.

In a steady-state condition, the two phases of the TPS53624 switch 180° out-of-phase. The phase displacement is maintained both by the architecture (which does not allow both hig-side gate drives to be on in any condition) and the current ripple (which forces the pulses to be spaced equally). The controller forces current sharing adjusting the on-time of each phase. Current balancing requires no user intervention, compensation, or extra components.

Multi-Phase, PWM Operation

Referring to the Functional Block Diagram and , in dual-phase steady state, continuous conduction mode, the converter operates as follows:

Starting with the condition that both high-side MOSFETs are off and both low-side MOSFETs are on, the summed current feedback (V_{CMP}) is higher than the error amplifier output (V_{DROOP}). V_{CMP} falls until it hits V_{DROOP} , which contains a component of the output ripple voltage. The PWM comparator senses where the two waveforms cross and triggers the on-time generator.

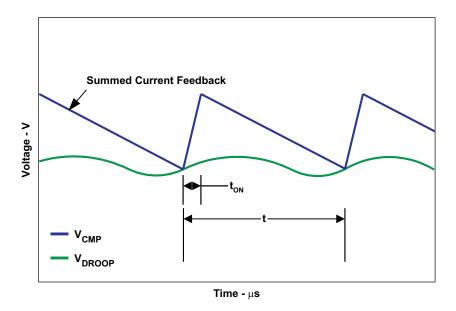

Figure 2. D-CAP+ Mode Basic Waveforms

The summed current feedback is an amplified and filtered version of the CSPx and CSNx inputs. The TPS53624 provides dual independent channels of current feedback to increase the system accuracy and reduce the dependence of circuit performance on layout compared to an externally summed architecture.

PWM Frequency and Adaptive on Time Control

The on-time (at the LL node) is determined by Equation 1.

$$t_{ON} = \left(\frac{V_{OUT}}{V_{IN}}\right) \times \left(\frac{1}{f_{SEL}}\right) + 30 \,\text{ns}$$

where

•
$$f_{SEL}$$
 is the frequency selected by the connection of the TONSEL pin (1)

The on-time pulse is sent to the high-side MOSFET. The inductor current and summed current feedback rise to their maximum value, and the multiplexer and de-multiplexer switch to the next phase. Each ON pulse is latched to prevent double pulsing.

The current sharing circuitry compares the average values of the individual phase currents, then adds or subtracts a small amount from each on-time in order to bring the phase currents into line. No user design is required.

Accurate droop is provided by the finite gain of the droop amplifier. The calculation for output voltage droop, V_{DROOP} is shown in Equation 2.

$$V_{DROOP} = \frac{R_{CS} \times A_{CS} \times \sum I(L)}{R_{DROOP} \times G_{M}}$$

where

- R_{CS} is the effective current sense resistance, regardless if a sense resistor or inductor DCR is used
- A_{CS} is the gain of the current sense amplifier
- ΣI(L) is the DC sum of inductor currents
- R_{DROOP} is the value of resistor from the DROOP pin to VREF
- G_M(droop) is the GM of the droop amplifier

(2)

(3)

The capacitor in parallel with R_{DROOP} matches the slew rate of the DROOP pin with the current feedback signals to prevent *ring-back* during transient load conditions.

$$C_{DROOP} = \frac{R_{LL} \times \Delta I_{OUT} \times g_{M} \times L}{R_{CS} \times A_{CS} \times D_{MAX} \times V\left(L\right)} - 30\,\text{pF}$$

where

- R_{LL} is load-line slope defined by proicessor mnufacturer
- ΔI_{OUT} is maximum dynamic load current for the processor
- $D_{MAX} = t_{ON} / t_{ON} + t_{OFF(min)}$
- V(L) is the voltage across the inductor (V_{BAT} V_{CORE}).

The 30-pF term accounts for the slew rate limit of the amplifier without external capacitance.

AutoBalance Current Sharing

The basic mechanism for current sharing is to sense the average phase current, then adjust the pulse width of each phase to equalize the current in each phase. The block diagram is shown in Figure 3.

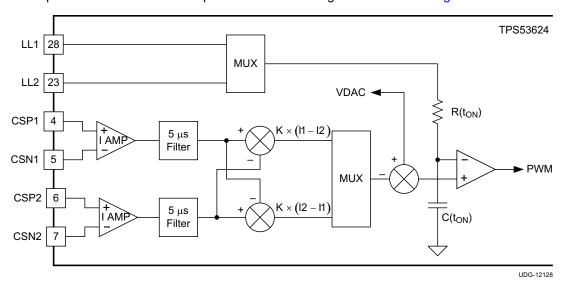

Figure 3. Current Sharing Block Diagram

Figure 3 also shows the TI D-CAP+ $^{\text{TM}}$ constant on-time modulator. The PWM comparator (not shown) starts a pulse when the feedback voltage meets the reference. This pulse turns on the gate of the high-side MOSFET. After the MOSFET turns on, the LL voltage for that phase is driven up to the battery input. This charges $C(t_{ON})$ through $R(t_{ON})$. The pulse is terminated when the voltage at $C(t_{ON})$ matches the t_{ON} reference, normally the DAC voltage (V_{DAC}) .

The circuit operates in the following fashion, using Figure 3 as the block diagram and to show the circuit action at the level of an individual pulse (PWM1). First assume that the 5 μ s averaged value of I1 = I2. In this case, the PWM modulator terminates at VDAC, and the normal pulse width is delivered to the system. If instead, I1 > I2, then an offset is subtracted from VDAC, and the pulse width for phase one is shortened, reducing the current in phase one to compensate. If I1 < I2, then a longer pulse is produced, again compensating on a pulse-by-pulse basis.

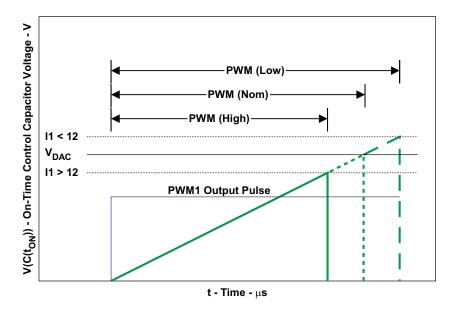

Figure 4.

Because the increase in pulse width is proportional to the difference between the actual phase current and the ideal current, the system converges smoothly to equilibrium. Because the filtering is so much lighter than conventional current sharing schemes, the settling time is very fast. Analysis shows the response to be single pole with a bandwidth of approximately 60 kHz.

The speed advantage of the TPS53624 is beneficial because processors quickly move from full speed to idle and back to save power when processing light and moderate loads. A multi-phase converter that takes milliseconds to implement current sharing is never in equilibrium and thermal hot-spots can result. The TPS53624 allows rapid dynamic current and output voltage changes while maintaining current balance.

Overshoot Reduction (OSR) Feature

The problem of overshoot in low duty-cycle synchronous buck converters results from the output inductor having a small voltage (V_{CORF}) with which to respond to a transient load release.

In Figure 5, a single phase converter is shown for simplicity. In an ideal converter, with the common values of 12-V input and 1.2-V output, the inductor has 10.8 V (12 V - 1.2 V) to respond to a transient step, and 1.2 V to respond once the load releases.

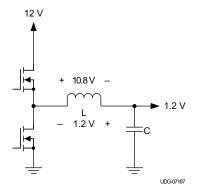

Figure 5. Synchronous Converter

Figure 6 shows a two-phase converter. The energy in the inductor is transferred to the capacitance on the V_{CORE} node above and the output voltage (green trace) overshoots the desired level (lower cursor, also green). In this case, the magnitude of the overshoot is approximately 40 mV. The LLx waveforms (yellow and blue traces) remain flat during the overshoot, indicating the DRVLx signals are on.

The performance of the same dual phase circuit, but with OSR enabled is shown in Figure 7. In this case, the low side FETs shut off when overshoot is detected and the energy in the inductor is partially dissipated by the body diodes. The overshoot is reduced by 25 mV. The dips in the LLx waveforms show the DRVLx signals are OFF only long enough to reduce the overshoot.

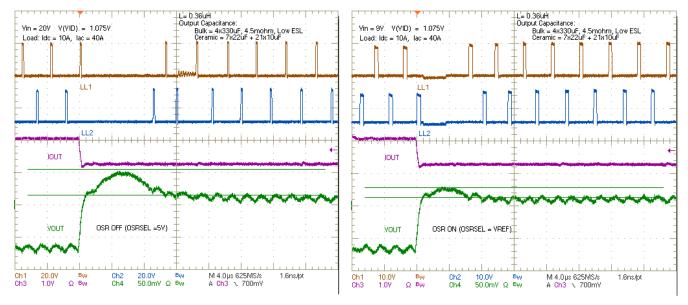

Figure 6. Circuit Performance Without Overshoot Reduction

Figure 7. Transient Release Performance Improved with Overshoot Reduction

Implementation

OSR is implemented using a comparator between the DROOP and ISUM nodes. To implement OSR, simply terminate the OSRSEL pin to the desired voltage to set the threshold voltage for the comparator. The settings are:

- GND = Minimum voltage (Maximum reduction)
- VREF = Medium voltage
- +3.3V = Maximum voltage
- 5V = OSR off

Use the highest setting that provides the desired level of overshoot reduction to eliminate the possibility of false OSR operation.

Light Load Power Saving Features

Submit Documentation Feedback

The TPS53624 has several power saving features to provide excellent efficiency over a very large load range. This feature is implemented with PCNT pin.. This pin is a VCCP I/O level. A LO on this pin puts the converter into single phase mode, thus eliminating the quiescent power of phase two when high power is not needed.

In addition, the TPS53624 has an automatic pulse skipping skip mode. Regardless of the state of the logic inputs, the converter senses negative inductor current flow and prevents it by shutting off the low-side MOSFET(s). This saves power by eliminating recirculating current.

MOSFET Drivers

The TPS53624 incorporates a pair of strong, high-performance gate drives with adaptive cross-conduction protection. The driver uses the state of the DRVLx and LLx pins to be sure the high-side or low-side MOSFET is off before turning the other on. Fast logic and high drive currents (up to 8 A typical!) quickly charge and discharge MOSFET gates to minimize dead-time to increase efficiency. The high-side gate driver also includes an internal P-N junction *boost* diode, decreasing the size and cost of the external circuitry. For maximum efficiency, this diode can be bypassed externally by connecting Schottky diodes from V5IN (anode) to VBSTx (cathode).

Voltage Slewing

The TPS53624 ramps the internal DAC up and down as the VID is changing. These timings are independent of switching frequency, as well as output resistive and capacitive loading. The slew rate is set by a resistor from the SLEW pin to AGND (R_{SLEW}). R_{SLEW} sets both the slew rate and the soft-start rate.

$$R_{SLEW} = \frac{K_{SLEW} \times V_{SLEW}}{SR}$$

where

- $K_{SLEW} = 1.25 \times 10^9$
- V_{SLEW} is equal to the slew reference V_{SLEWREF} when R_{SLEW} is tied to GND (4)

Connecting R_{SLEW} to VREF enables the high range of overcurrent protection and changes V_{SLEW} in Equation 4 to 0.45 V (VREF – $V_{SLEWREF}$). The soft-start rate is 1/8 the slew rate.

At start-up the VID code should be stable at the time EN goes high. For example, the V_{VID} for IMVP6.5 is 1.1 V. The soft-start time to V_{BOOT} is shown in Equation 5.

$$t_{SS} = \frac{1.1V \times 8}{SR} (s)$$
 (5)

Protection Features

The TPS53624 features full protection of the converter power chain as well as the system electronics.

Input Undervoltage Protection (UVLO)

The TPS53624 continuously monitors the voltage on the V5FILT pin to ensure the value is high enough to bias the devices properly and provide sufficient gate drive potential to maintain high efficiency. The converter starts with approximately 4.4 V and has a nominal 200 mV of hysteresis. This function is not latched, therefore removing and restoring 5-V power to the device resets it. The power input (V_{IN}) does not include a UVLO function, so the circuit runs with power inputs down to approximately $3 \times V_{CORE}$.

Power Good Signals

The TPS53624 has two open-drain powergood pins. PGD and PG have the following nominal thresholds:

- High: V_{DAC} + 200 mV
- Low: V_{DAC} 300 mV

The differences are:

- PG transitions active low shortly (approximately 50 μs) after V_{OUT} reaches the V_{ID} voltage on power-up.
- PGD rises at the same time as \overline{PG} reaches the power good threshold defined above. PGD is high when power is good and low when power is not good.

Both power good signals go inactive when the EN pin is pulled low or an undervoltage condition on V5IN is detected. Both are also *masked* during DAC transitions to prevent false triggering during voltage slewing.

Output Overvoltage Protection (OVP)

In addition to the power good function described above, the TPS53624 has additional OVP and UVP thresholds and protection circuits.

An OVP condition is detected when VOUT is > 200 mV greater than V_{DAC} . In this case, the converter sets PGD signals inactive and then latches OFF. The converter remains in this state until the device is reset by cycling either V5IN or EN

However, because of the dynamic nature of VR systems, the +200 mV OVP threshold is *blanked* much of the time. In order to provide protection to the processor 100% of the time, there is a second OVP level fixed at 1.55 V which is always active. If the fixed OVP condition is detected, the PGD signals are forced inactive and the DRVLx signals are driven HI. The converter remains in this state until either V5IN or EN are cycled.

Output Undervoltage Protection (UVP)

Output undervoltage protection works in conjunction with the current protection described below. If VOUT drops below the low PGD threshold for 80 µs, then the drivers are turned OFF until either V5IN or EN are cycled.

Current Protection

Two types of current protection are provided in the TPS53624.

- Overcurrent protection (OCP)
- Negative overcurrent protection

Overcurrent Protection (OCP)

The TPS53624 uses a *valley* current limiting scheme, so the ripple current must be considered. The DC current value at OCP is the OCP limit value plus half of the ripple current. Current limiting occurs on a phase-by-phase and pulse-by-pulse basis. If the voltage between CSPx and CSNx is above the OCP value (selected by combination of TRIPSEL pin connection and R_{SLEW} termination), the converter holds off the next ON pulse until it drops below the OCP limit. For inductor current sensing circuits, the voltage between CSPx and CSNx is the inductor DCR value multiplied by the resistor divider which is part of the NTC compensation network. As a result, a wide range of OCP values can be obtained by changing the resistor divider value. In general, use the highest TRIPSEL setting possible with the least attenuation in the resistor divider to provide as much signal to the device as possible. This provides the best performance for all parameters related to current feedback.

In OCP mode, the voltage droops until the UVP limit is reached. Then, the converter sets the PGD pins inactive, and the drivers are turned OFF. The converter remains in this state until the device is reset by the EN or the V5IN pin.

Settings use both the TRIPSEL pin and the R_{SLEW} termination. The eight possible OCP settings are shown in Table 4. For the levels in mV for a specific setting, see the *Electrical Characteristics* table.

Table 4. TRIPSEL Settings

ОСР		R _{SLEW} Tie	ed to GND		R _{SLEW} Tied to VREF					
TRIPSEL	GND	VREF	3.3V	5V	GND	VREF	3.3V	5V		
Setting Level	1	2	3	4	5	6	7	8		

Negative Overcurrent Protection

The negative OCP circuit acts when the converter is sinking current. The converter continues to act in a *valley* mode, so to have a similar negative DC limit, the absolute value of the negative OCP set point is typically 50% higher than the positive OCP set point.

Thermal Protection

Two types of thermal protection are provided in the TPS53624

- Thermal flag open drain ouptut signal (THAL)
- · Thermal shutdown

Thermal Flag Open Drain Ouptut Signal THAL

The \overline{THAL} signal is an Intel-defined open-drain signal that is used to protect the power chain. To use \overline{THAL} , place an NTC thermistor at the hottest area of the PC board and connect it to the THRM pin. THRM sources a precise 60- μ A current, and \overline{THAL} goes LO when the voltage on THERM reaches 0.7 V. Therefore, the NTC thermistor needs to be 11.7 k Ω at the trip level. A series or parallel resistor can be used to trim the resistance to the desired value at the trip level.

THAL signal does not change the operation of TPS53624

Thermal Shutdown

The TPS53624 also has an internal temperature sensor. When the temperature reaches a nominal 160°C, the device shuts down. The converter remains in this state until either V5IN or EN is cycled.

Current Monitor

The TPS53624 includes a power monitor function. The power monitor puts out an analog voltage proportional to the output power on the IMON pin.

$$V_{IMON} = A_{CS} \times GM_{IMON} \times \sum V_{CS} = K_{IMON} \times \sum V_{CS}$$

where

- K_{IMON} is given in the *Electrical Characteristics* table
- Σ V_{CS} is the sum of the voltages at the inputs to the current sense amplifiers

(6)

Single-Phase Operation

The TPS53624 is a two-phase controller. This controller can also be configured for single-phase operation. There are two ways the controller operates in single-phase mode.

- PCNT = 0 V. In this case, the controller starts up as dual-phase but goes into single-phase after start-up is completed. This mode is used for improving efficiency of a two-phase converter while operating under light load conditions.
- PCNT = 5 V. In this case, the controller operates in a complete single-phase mode. The drivers for Phase 2 are totally disabled in this mode.

In order to use the controller purely as a single-phase controller, connect PCNT to V5FILT. Also, the current sense input pins of the second phase (CSN2, CSP2) must be grounded. All the other pins of the second phase must be left open.

VID Table

The TPS53624 incorporates the 8-bit VID table shown in Table 5.

APPLICATION INFORMATION

Design Procedure

The TPS53624 has the simplest design procedure of any IMVP6.5 CORE controller on the market.

Choosing Initial Parameters

Step One

Determine the processor specifications. For the purposes of this document, the Intel® Auburndale 45-V Processor from Table 2 of the RS – Intel® IMVP-6.5 Mobile Processor and Mobile Chipset Voltage Regulation Specification, Reference Number 24779, Revision 1.0 is used.

The processor requirements provide the following key parameters.

- V_{HFM} = 1.075 V
- $R_{IMVP} = -1.9 \text{ m}\Omega$
- $I_{CC(max)} = 50 \text{ A}$
- I_{DYN(max)} = 35 A
- I_{CC(tdc)} = 37 A
- Slew rate = 5 mV/µs (minimum)

The last requirement shows that the converter must support a 25% overcurrent for 10 µs without going out of tolerance. The TPS53624 is designed to support the momentary OCP requirement internally, so only the DC OCP limit needs to be considered when calculating OCP levels. This also means that the power-chain does not have to be over-designed to meet Intel requirements.

Step Two

Determine system parameters.

The input voltage range and operating frequency are of primary interest.

For example

- V_{IN(max)} = 20 V
- V_{IN(min)} = 9 V
- f_{SW} = 300 kHz

Step Three

Determine current sensing method.

The TPS53624 supports both resistor sensing and inductor DCR sensing. Inductor DCR sensing is chosen.

For resistor sensing, substitute the resistor value (1 m Ω recommended for a 50-A application) for R_{CS} in the subsequent equations and skip Step Five.

Step Four

Determine inductor value and choose inductor.

Smaller inductor values have better transient performance but higher ripple and lower efficiency. Higher values have the opposite characteristics. It is common practice to limit the ripple current to between 30% and 50% of the maximum current per phase. In this case, use 40%:

$$I_{P-P} = \frac{50 \,\mathrm{A}}{2 \,\mathrm{phases}} \times 0.4 = 10 \,\mathrm{A} \tag{7}$$

At f_{SW} = 300 kHz, with a 20-V input and a 1.075-V output.

$$L = \frac{V \times dT}{I_{P-P}}$$

where

$$V = \left(V_{IN(max)} - V_{HFM}\right)$$

$$dT = \left(\frac{V_{HFM}}{\left(f \times V_{IN(max)}\right)}\right)$$
(8)

L=0.34 µH

An inductance value of $0.36~\mu H$ is chosen. Ensure that the inductor does not saturate during peak loading conditions.

$$I_{SAT} = \left(\frac{I_{CC(max)}}{N_{PHASE}} + \frac{I_{P-P}}{2}\right) \times 1.2 \times 1.25 = 45 \text{ A}$$
(9)

The factor of 1.2 is included to allow for current sensing and current limiting tolerances. The factor of 1.25 is due to Intel's 25% momentary OCP requirement described above.

The chosen inductor should have the following characteristics:

- As flat an inductance vs. current curve as possible. Inductor DCR sensing is based on the idea L/DCR is approximately a constant through the current range of interest.
- Either high saturation or soft saturation
- Low DCR for improved efficiency, but at least 0.7 mΩ for proper signal levels.
- DCR tolerance as low as possible for load-line accuracy.

For this application, a 0.36-μH, 1.0-mΩ inductor is chosen.

Step Five

Design the thermal compensation network.

In most designs, NTC thermistors are used to compensate thermal variations in the resistance of the inductor winding. This winding is generally copper, and therefore has a resistance coefficient of 3900 PPM/°C. NTC thermistors, however, have very non-linear characteristics and need two or three resistors to linearize them over the range of interest. The typical DCR circuit is shown in Figure 8.

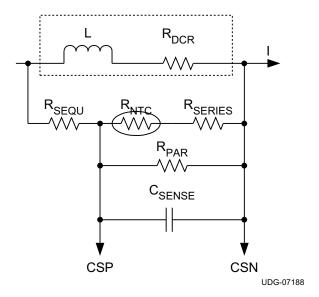

Figure 8. Typical DCR Sensing Circuit

In this circuit, good performance is obtained when:

$$\frac{L}{R_{DCR}} = C_{SENSE} \times R_{EQ} \tag{10}$$

In Equation 10, all of the parameters are defined in Figure 8 except R_{EQ} , which is the series/parallel combination of the other four discrete resistors. C_{SENSE} should be a capacitor type which is stable over temperature. Use X7R or better dielectric (C0G preferred).

Because calculating these values by hand is difficult, TI offers a spreadsheet using the Excel *Solver* function. Contact your local TI representative to get a copy of the spreadsheet.

In the reference design, the following values are input to the spreadsheet:

- L = 0.36 µH
- $R_{DCR} = 1 \text{ m}\Omega$
- Load Line (typically -1.9 mΩ for SV processors)
- Minimum overcurrent limit = 56 A
- Thermistor R₂₅ and "B" value = 4700 kΩ

The spreadsheet then calculates the TRIPSEL setting and the values of:

- R_{SEQU}
- R_{SERIES}
- R_{PAR}
- C_{SENSE}

In this case, the TRIPSEL setting is TRIPSEL = 5 V with R_{SLEW} to GND and the nearest standard component values are:

- $R_{SERIES} = 43.2 \text{ k}\Omega$
- $R_{PAR} = 143 \text{ k}\Omega$
- $R_{SEQU} = 24.3 \text{ k}\Omega$
- C_{SENSE} = 18 nF

Note the effective divider ratio for the inductor DCR. The effective current sense resistance ($R_{CS(eff)}$) is shown in Equation 11.

$$R_{CS(eff)} = R_{DCR} \times \frac{R_{P_N}}{R_{SEQU} + R_{P_N}}$$

where

• $R_{P N}$ is the series/parallel combination of $R_{NTC}R_{SERIES}$ and R_{PAR} (11)

$$R_{P-N} = \frac{R_{PAR} \times (R_{NTC} + R_{SERIES})}{R_{PAR} + R_{NTC} + R_{SERIES}}$$
(12)

 $R_{CS(eff)}$ is 0.77 m Ω .

Step Six

Determine the output capacitor configuration.

Intel has several recommended configurations in the specifications. The TPS53624 meets every requirement with margin using the minimum configuration given in the Intel specification (Option 3). Depending on the layout, it is possible to reduce the output capacitance further, or to use alternate capacitor technologies. A good rule of thumb is that a successful design has a combination of bulk and ceramic capacitance totaling at least 1600 µF.

Step Seven

Set the load line.

The load line is set by the droop resistor using R_{IMVP} and R_{CS(eff)}.

$$R_{DROOP} = \frac{R_{CS(eff)} \times A_{CS}}{G_{M} \times R_{IMVP}} = 4.75 \text{k}\Omega$$
(13)

Step Eight

Calculate the droop capacitor value.

$$C_{DROOP} = \frac{R_{LL} \times \Delta I_{OUT} \times g_{M} \times L}{R_{CS} \times A_{CS} \times D_{MAX} \times V(L)} - 30 \, pF = 105 \, pF$$
(14)

Because better overall transient performance is obtained by allowing a small ring-back, a small value capacitor (between 33 pF and 68 pF) is used. This capacitor also helps in eliminating any noise that may be present at the DROOP pin.

Step Nine

Calculate RSI FW.

 R_{SLEW} sets the slew rate and the soft-start rate. The soft-start rate is 1/8 of the slew rate. Given the Intel requirements, the slew rate minimum requirement is 5 mV/ μ s.

$$R_{SLEW} = \frac{K_{SLEW} \times V_{SLEW}}{SR}$$

here

From the overcurrent limit setting in Step Five, R_{SLEW} is terminated to GND

•
$$K_{SLEW} = 1.25 \times 10^9$$

• $V_{SLEW} = 1.25 \text{ V}$ (15)

Taking into account the tolerance on K_{SLEW} , $R_{SLEW} = 250 \text{ k}\Omega$.

Submit Documentation Feedback

(16)

www.ti.com SLUSB66 – MARCH 2013

Step Ten

Calculate R_{IMON}.

R_{IMON} is calculated to set the voltage on the IMON pin to approximately 1.0 V at maximum processor current.

$$R_{IMON} = \frac{V_{IMON}}{K_{IMON} \times I_{CC(max)} \times R_{CS(eff)}} \left(\Omega\right)$$

here

- V_{IMON} = 1.0 V
- $K_{IMON} = 2 \mu A/mV$
- $I_{CC(max)} = 50 \text{ A}$
- $R_{CS(eff)} = 0.77 \text{ m}\Omega$
- $R_{IMON} = 13.1 \text{ k}\Omega$
- C_{IMON} = 3300pF and is added in parallel to R_{IMON} to give a smooth response on IMON pin.

Step Eleven

Calculate THAL pin components.

The THERM pin produces a nominal 61 μ A current. The trip voltage is 0.75 V. Therefore, the resistance at the trip point needs to be 0.75V / 61 μ A = 12.3 k Ω . For a trip temperature of 85°C, the recommended 150 k Ω NTC thermistor is 10.3 k Ω . To move the trip point to the correct resistance, we add a series resistance of 2.0 k Ω . Depending on the thermistors selection and desired trip point, adding a parallel resistance to obtain the correct resistance at the trip point is also possible. In order to keep the sensing as accurate as possible in both cases, the contribution of the fixed resistance at the trip point should be as small as possible.

- V5IN decoupling ≥ 2.2 μF, ≥ 10 V
- V5FILT decoupling ≥ 1 μF, ≥ 10 V
- VREF decoupling 0.22 µF to 1 µF, ≥ 4 V
- Bootstrap capacitors ≥ 0.22 μF, ≥ 10 V Bootstrap diodes (optional) 30 V Schottky diode, BAT-54 or better
- Pull-up resistors on PGOOD, PG. THAL, and PCNT pins per Intel guidelines

For power chain and other component selection, see Table 2.

Step Twelve

Select decoupling and peripheral components.

For peripheral capacitors use the following minimum values of ceramic capacitance. A capacitor with an X5R or better temperature coefficient is recommended. Tighter tolerances and higher voltage ratings are always appropriate.

- V5IN decoupling ≥ 2.2 µF, ≥ 10V
- V5FILT decoupling ≥ 1 µF, ≥ 10V
- VREF decoupling 0.22 µF to 1 µF, ≥ 4 V
- Bootstrap capacitors ≥ 0.22 µF, ≥ 10 V
- Bootstrap diodes (optional) 30 V Schottky diode, BAT-54 or better
- Pull-up resistors on PGOOD, PG, THAL, and PCNT pins per Intel guidelines

Layout Guidelines

The TPS53624 has fully differential current and voltage feedback. As a result, no special layout considerations are required. However, all high-performance multi-phase power converters, like the TPS53624, require a certain level of care in layout.

Schematic Review

Because the voltage and current feedback signals are fully differential it is a good idea to double check the polarity.

- CSP1 / CSN1
- CSP2 / CSN2
- VCCSENSE to VFB / VSSSENSE to GSNS

Specific Guidelines

Separate Noisy Driver Interface Lines from Sensitive Analog Interface Lines

The TPS53624 makes this as easy as possible, as the two sets of pins are on opposite sides of the device. In addition, the CPU interface signals are grouped on one side of the device, and the MCH and platform interface signals are grouped on the opposite side. This arrangement is shown in Figure 9.

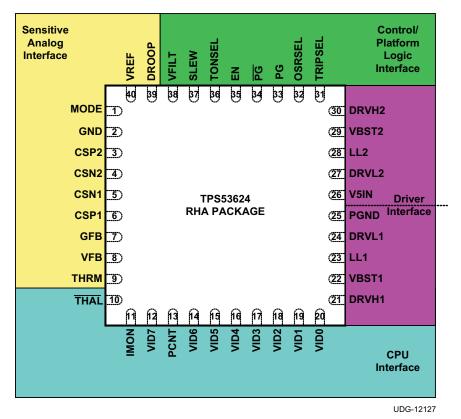

Figure 9. Device Layout by Pin Function

Given the physical layout of most systems, the current feedback (CSPx, CSNx) may have to pass near the power chain. Clean current feedback is required for good load-line, current sharing, and current limiting performance of the TPS53624. This requires the designer take the following precautions.

- Make a Kelvin connection to the pads of the resistor or inductor used for current sensing. See Figure 10 for a layout example.
- Lay out the current feedback signals as a differential pair to the device.
- Lay out the lines in a quiet layer. Isolate them from noisy signals by a voltage or ground plane.

- Design the compensation capacitor for DCR sensing (C_{SENSE}) as close to the CS pins as possible.
- Place R_{PAR} near C_{SENSE}.
- Place any noise filtering capacitors directly under the TPS53624 and connect to the CS pins with the shortest trace length possible.

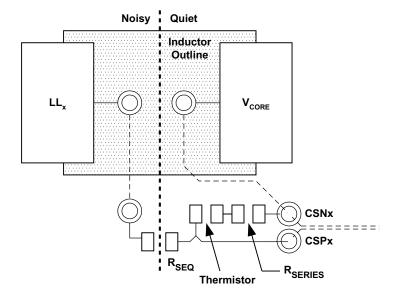

Figure 10. Make Kelvin Connections to the Inductor for DCR Sensing

UDG-07189

- Ensure that all vias in the CSPx and CSNx traces are isolated from all other signals
- Lay out the dotted signal traces in internal planes
- If possible, change the name of the CSNx trace to prevent unintended connections to the V_{CORE} plane
- · Design CSPx and CSNx as a differential pair in a quiet layer
- Design the capacittor as near to the device pins as possible

Product Folder Links: *TP*S53624

Minimize High Current Loops

Figure 11 shows the primary current loops in each phase, numbered in order of importance. The most important loop to minimize the area of is Loop 1, the path from the input capacitor through the high and low-side MOSFETs, and back to the capacitor through ground.

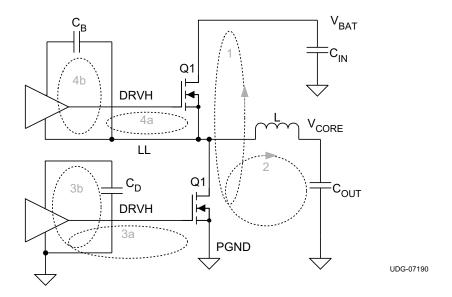

Figure 11. Major Current Loops Requiring Minimization

Loop 2 is from the inductor through the output capacitor, ground and Q2. The layout of the low-side gate drive (Loops 3a and 3b) is important. The guidelines for gate drive layout are:

- Make the low side gate drive as short as possible (1 inch or less preferred).
- Make the DRVL width to length ratio of 1:10, wider (1:5) if possible
- · If changing layers is necessary, use at least two vias

Submit Documentation Feedback

Power Chain Symmetry

The TPS53624 does not require special care in the layout of the power chain components, because independent isolated current feedback is provided. Make every effort to lay out the phases in a symmetrical manner. The current feedback from each phase must be free of noise and have the same effective current sense resistance. A value of 1 m Ω of current feedback resistance is recommended.

Place Analog Components as Close to the Device as Possible

Place components close to the device in the following order.

- 1. CS pin noise filtering components
- 2. DROOP pin compensation component
- 3. Decoupling capacitor
- 4. SLEW resistor (R_{SLEW})

Grounding Recommendations

The TPS53624 has separate analog and power grounds, and a thermal pad. The normal procedure for connecting these is:

- 1. Connect the thermal pad to PGND.
- 2. Tie the thermal pad to the system ground plane with at least 4 small vias or one large via.
- 3. GND can be connected to any quiet space. A quiet space is defined as a spot where no power supply switching currents are likely to flow. This applies to both the VCORE regulator and other regulators. Use a single point connection to the point, and pour a GND island around the analog components.
- 4. Make sure the low-side MOSFET source connection and the decoupling capacitors have plenty of vias.

Decoupling Recommendations

- Decouple V5 to PGND with at least a 2.2-µF ceramic capacitor. This fits best on the opposite side of the
 device.
- · Use double vias to connect to the device.
- Decouple V5FILT with 1-uF to AGND with leads as short as possible.
- Decouple VREF to AGND with 0.22-µF, with short leads as short as possible.

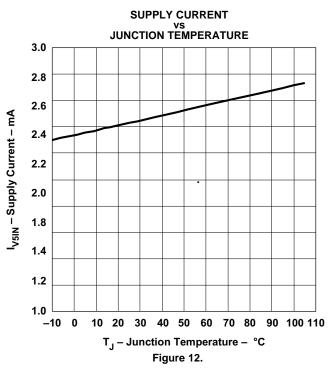

Conductor Widths

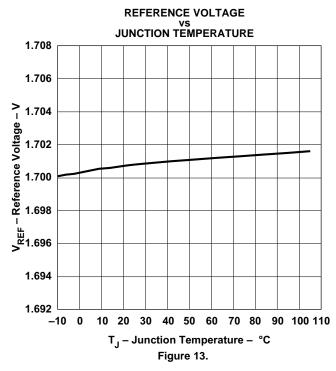

- Follow Intel guidelines with respect to the voltage feedback and logic interface connection requirements.
- Maximize the widths of power, ground and drive signal connections.
- For conductors in the power path, be sure there is adequate trace width for the amount of current flowing through the traces.
- Make sure there are sufficient vias for connections between layers.
- Use a minimum of 1 via per ampere of current

TPS53624RHAT	PREVIEW	VQFN	RHA	40	250	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-3-260C-168 HR	

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check http://www.ti.com/productcontent for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

- NOTES: A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M—1994.
 - B. This drawing is subject to change without notice.
 - C. QFN (Quad Flatpack No-Lead) Package configuration.
 - D. The package thermal pad must be soldered to the board for thermal and mechanical performance.
 - E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
 - F. Package complies to JEDEC MO-220 variation VJJD-2.

RHA (S-PVQFN-N40)

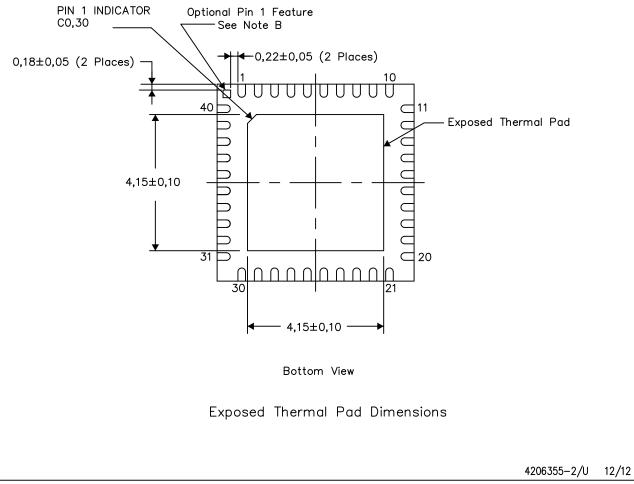

PLASTIC QUAD FLATPACK NO-LEAD

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

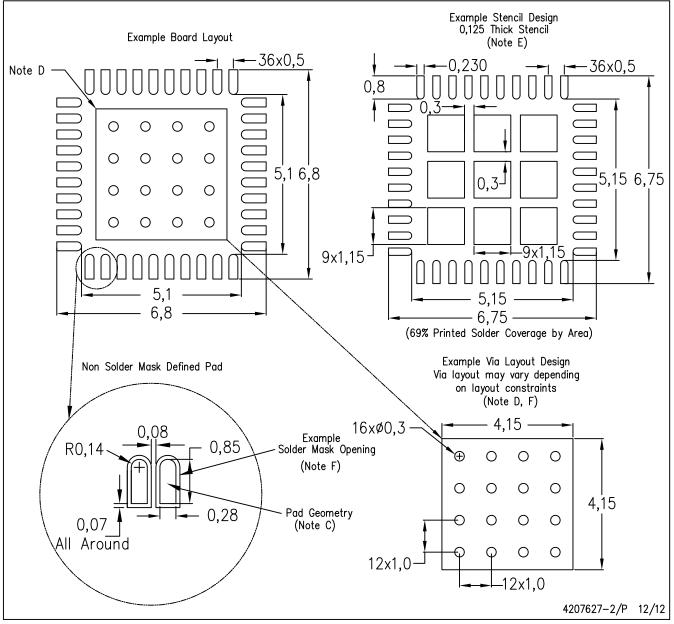

NOTES: A. All linear dimensions are in millimeters

B. The Pin 1 Identification mark is an optional feature that may be present on some devices In addition, this Pin 1 feature if present is electrically connected to the center thermal pad and therefore should be considered when routing the board layout.

RHA (S-PVQFN-N40)

PLASTIC QUAD FLATPACK NO-LEAD

NOTES:

- A. All linear dimensions are in millimeters.
- B. This drawing is subject to change without notice.
- C. Publication IPC-7351 is recommended for alternate designs.
- D. This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, Quad Flat—Pack Packages, Texas Instruments Literature No. SLUA271, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com http://www.ti.com>.
- E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
- F. Customers should contact their board fabrication site for recommended solder mask tolerances and via tenting recommendations for vias placed in the thermal pad.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have *not* been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
