

1.5A/4.1A Multiple LED Camera Flash Driver With I²C™ Compatible Interface

Check for Samples: [TPS61300](#), [TPS61301](#), [TPS61305](#), [TPS61305A](#)

FEATURES

- Four Operational Modes
 - DC Light and Flashlight
 - Voltage Regulated Converter: 3.8V...5.7V
 - Standby: 2μA (typ.)
- Storage Capacitor Friendly Solution
- Automatic V_F and ESR Calibration
- Power-Save Mode for Improved Efficiency at Low Output Power, Up to 95% Efficiency
- Output Voltage Remains Regulated When Input Voltage Exceeds Nominal Output Voltage
- I²C Compatible Interface up to 3.4Mbits/s
- Zero Latency Tx-Masking Input
- Hardware Voltage Mode Selection Input (TPS61300, TPS61301)
- DC Light Mode Selection Input (TPS61300, TPS61306)
- Hardware Reset Input (TPS61301, TPS61305)
- LED Temperature Monitoring (TPS61305)
- Privacy Indicator LED Output
- Integrated LED Safety Timer
- Total Solution Size of Less Than 25 mm² (<1mm height)
- Available in a 20-Pin NanoFree™ (CSP)

APPLICATIONS

- Single/Dual/Triple White LED Flashlight Supply for Cell Phones and Smart-Phones
- LED Based Xenon "Killer" Flashlight
- Audio Amplifier Power Supply

DESCRIPTION

The TPS6130x device is based on a high-frequency synchronous boost topology with constant current sinks to drive up to three white LEDs in parallel (400mA/800mA/400mA maximum flash current). **The extended high-current mode (HC_SEL) allows up to 1025mA/2050mA/1025mA flash current out of the storage capacitor.**

The high-capacity storage capacitor on the output of the boost regulator provides the high-peak flash LED current, thereby reducing the peak current demand from the battery to a minimum.

The 2-MHz switching frequency allows the use of small and low profile 2.2μH inductors. To optimize overall efficiency, the device operates with a 400mV LED feedback voltage.

The TPS6130x device not only operates as a regulated current source, but also as a standard voltage boost regulator. The device keeps the output voltage regulated even when the input voltage exceeds the nominal output voltage. The device enters power-save mode operation at light load currents to maintain high efficiency over the entire load current range.

To simplify flashlight synchronization with the camera module, the device offers a trigger pin (FLASH_SYNC) for zero latency LED turn-on time.

Figure 1. Typical Application

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

NanoFree is a trademark of Texas Instruments.

I²C is a trademark of NXP Semiconductors.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of the Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

Copyright © 2009–2012, Texas Instruments Incorporated

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

AVAILABLE OPTIONS

PART NUMBER ⁽¹⁾	PACKAGE MARKING	PACKAGE	DEVICE SPECIFIC FEATURES ⁽²⁾
TPS61300YFF	TPS61300	CSP-20	Hardware Enable DC Light Input (ENDCL)
TPS61301YFF	TPS61301	CSP-20	Hardware Enable / Disable Input (NRESET)
TPS61305YFF	TPS61305	CSP-20	Hardware Enable / Disable Input (NRESET) LED Temperature Monitoring Input (TS)
TPS61305AYFF	TPS61305A	CSP-20	Hardware Enable / Disable Input (NRESET) LED Temperature Monitoring Input (TS)
TPS61306YFF ⁽³⁾	TPS61306	CSP-20	Hardware Enable DC Light Input (ENDCL) LED Temperature Monitoring Input (TS)

- (1) The YFF package is available in tape and reel. Add R suffix (TPS6130xYFFR) to order quantities of 3000 parts per reel, T suffix for 250 parts per reel.
(2) For more details, refer to the section *Application Diagrams*.
(3) Device status is Product Preview. Please contact TI for more details.

ABSOLUTE MAXIMUM RATINGS

over operating free-air temperature range (unless otherwise noted) ⁽¹⁾

		VALUE	UNIT
V _I	Voltage range on AVIN, VOUT, SW, LED1, LED2, LED3 ⁽²⁾	–0.3 to 7	V
	Voltage range on SCL, SDA, FLASH_SYNC, ENDCL, NRESET, ENVM, GPIO/PG ⁽²⁾	–0.3 to 7	V
	Voltage range on HC_SEL, Tx-MASK, TS, BAL ⁽²⁾	–0.3 to 7	V
	Current on GPIO/PG	±25	mA
	Power dissipation	Internally limited	
T _A ⁽³⁾	Operating ambient temperature range	–40 to 85	°C
T _J (MAX)	Maximum operating junction temperature	150	°C
T _{stg}	Storage temperature range	–65 to 150	°C
ESD rating ⁽⁴⁾	Human body model	2	kV
	Charge device model	500	V
	Machine model	100	V

- (1) Stresses beyond those listed under *absolute maximum ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *recommended operating conditions* is not implied. Exposure to absolute–maximum–rated conditions for extended periods may affect device reliability.
(2) All voltage values are with respect to network ground terminal.
(3) In applications where high power dissipation and/or poor package thermal resistance is present, the maximum ambient temperature may have to be derated. Maximum ambient temperature [T_{A(max)}] is dependent on the maximum operating junction temperature [T_{J(max)}], the maximum power dissipation of the device in the application [P_{D(max)}], and the junction-to-ambient thermal resistance of the part/package in the application (θ_{JA}), as given by the following equation: T_{A(max)} = T_{J(max)} – (θ_{JA} × P_{D(max)})
(4) The human body model is a 100-pF capacitor discharged through a 1.5-kΩ resistor into each pin. The machine model is a 200-pF capacitor discharged directly into each pin.

DISSIPATION RATINGS

PACKAGE	THERMAL RESISTANCE ⁽¹⁾ θ _{JA}	THERMAL RESISTANCE ⁽¹⁾ θ _{JB}	POWER RATING T _A = 25°C	DERATING FACTOR ABOVE ⁽²⁾ T _A = 25°C
YFF	71°C/W	21°C/W	1.4 W	14mW/°C

- (1) Simulated with high-K board
(2) Maximum power dissipation is a function of T_{J(max)}, θ_{JA} and T_A. The maximum allowable power dissipation at any allowable ambient temperature is P_D = (T_{J(max)} – T_A) / θ_{JA}.

ELECTRICAL CHARACTERISTICS

Unless otherwise noted the specification applies for $V_{IN} = 3.6V$ over an operating junction temp. $-40^{\circ}C \leq T_J \leq 125^{\circ}C$; Circuit of Parameter Measurement Information section (unless otherwise noted). Typical values are for $T_J = 25^{\circ}C$.

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
SUPPLY CURRENT						
V_{IN}	Input voltage range		2.5		5.5	V
I_Q	Operating quiescent current into AVIN	$I_{OUT} = 0$ mA, device not switching $-40^{\circ}C \leq T_J \leq +85^{\circ}C$		590	700	μA
		$I_{OUT(DC)} = 0$ mA, PWM operation $V_{OUT} = 4.95V$, voltage regulation mode		11.3		mA
I_{SD}	Shutdown current	HC_SEL = 0, $-40^{\circ}C \leq T_J \leq +85^{\circ}C$		1	5	μA
I_{STBY}	Standby current	HC_SEL = 1, storage capacitor balanced $-40^{\circ}C \leq T_J \leq +85^{\circ}C$		2	12	μA
	Pre-charge current	$V_{OUT} = 2.3V$, $2.5V \leq V_{IN} \leq 5.5V$	150			mA
	Pre-charge hysteresis (referred to V_{OUT})		40	75		mV
V_{UVLO}	Undervoltage lockout threshold (analog circuitry)	V_{IN} falling		2.3	2.4	V
OUTPUT						
V_{OUT}	Output voltage range	Current regulation mode	V_{IN}		5.5	V
		Voltage regulation mode	3.825		5.7	V
	Internal feedback voltage accuracy	$2.5V \leq V_{IN} \leq 4.8V$, $-20^{\circ}C \leq T_J \leq +125^{\circ}C$ Boost mode, PWM voltage regulation	-2%		2%	
	Power-save mode ripple voltage	$I_{OUT} = 10$ mA		0.015 V_{OUT}		V_{P-P}
OVP	Output overvoltage protection	V_{OUT} rising, $0000 \leq OV[3:0] \leq 0100$	4.5	4.65	4.8	V
		V_{OUT} rising, $0101 \leq OV[3:0] \leq 1111$	5.8	6.0	6.2	V
	Output overvoltage protection hysteresis	V_{OUT} falling, $0101 \leq OV[3:0] \leq 1111$		0.15		V
POWER SWITCH						
$r_{DS(on)}$	Switch MOSFET on-resistance	$V_{OUT} = V_{GS} = 3.6$ V		90		m Ω
	Rectifier MOSFET on-resistance	$V_{OUT} = V_{GS} = 3.6$ V		135		m Ω
$I_{lkg(SW)}$	Leakage into SW	$V_{OUT} = 0V$, SW = 3.6V, $-40^{\circ}C \leq T_J \leq +85^{\circ}C$		0.3	4	μA
I_{lim}	Rectifier valley current limit (open-loop)	$V_{OUT} = 4.95V$, HC_SEL = 0 $-20^{\circ}C \leq T_J \leq +85^{\circ}C$ PWM operation, relative to selected ILIM	-15		+15	%
OSCILLATOR						
f_{OSC}	Oscillator frequency			1.92		MHz
f_{ACC}	Oscillator frequency		-10		+7	%
THERMAL SHUTDOWN, HOT DIE DETECTOR						
	Thermal shutdown ⁽¹⁾		140	160		$^{\circ}C$
	Thermal shutdown hysteresis ⁽¹⁾			20		$^{\circ}C$
	Hot die detector accuracy ⁽¹⁾		-8		8	$^{\circ}C$

(1) Verified by characterization. Not tested in production.

PIN ASSIGNMENTS

CSP-20 (TOP VIEW)

CSP-20 (BOTTOM VIEW)

PIN FUNCTIONS (TPS61300)

PIN		I/O	DESCRIPTION
NAME	NO.		
AVIN	E4	I	This is the input voltage pin of the device. Connect directly to the input bypass capacitor.
VOUT	A2	O	This is the output voltage pin of the converter.
LED1	E2	I	LED return input. This feedback pin regulates the LED current through the internal sense resistor by regulating the voltage across it. The regulation operates with typically 400mV (HC_SEL = L) or 400mV (HC_SEL = H) dropout voltage. Connect to the cathode of the LEDs.
LED2	E1	I	
LED3	E3	I	
FLASH_SYNC	B4	I	Flashlight strobe pulse synchronization input. FLASH_SYNC = LOW: The device is operating and regulating the LED current to the DC light current level (DCLC). FLASH_SYNC = HIGH: The device is operating and regulating the LED current to the flashlight current level (FC).
HC_SEL	B3	I	Extended high-current mode selection input. This pin must not be left floating and must be terminated. HC_SEL = LOW: LED direct drive mode. The power stage is active and the maximum LED currents are defined as 400mA/800mA/400mA (ILED1/ILED2/ILED3). HC_SEL = HIGH: Energy storage mode. In flash mode, the power stage is either active with reduced current capability or disabled. The maximum LED current is defined as 925mA/1850mA/925mA (ILED1/ILED2/ILED3).
SCL	B2	I	Serial interface clock line. This pin must not be left floating and must be terminated.
SDA	B1	I/O	Serial interface address/data line. This pin must not be left floating and must be terminated.
GPIO/PG	D4	I/O	This pin can either be configured as a general purpose input/output pin (GPIO) or either as an open-drain or a push-pull output to signal when the converters output voltage is within the regulation limits (PG). Per default, the pin is configured as an open-drain power-good output.
ENVM	C4	I	Enable pin for voltage mode converter. Pulling this pin high forces the device into voltage regulation mode (V _{OUT} is preset to a fixed value, 4.95V).
INDLED	A1	O	This pin provides a constant current source to drive low V _F LEDs. Connect to LED anode.
ENDCL	D3	I	Hardware control pin for DC light operation. Pulling this pin high forces the device into DC light operation. The ENDCL input is only active when the device is programmed into shutdown or voltage mode regulation. LED1-3 inputs are controlled according to ENLED[3:1] bit settings.
Tx-MASK	C3	I	RF PA synchronization control input. Pulling this pin high turns the LED from flashlight to DC light operation, thereby reducing almost instantaneously the peak current loading from the battery.
SW	C1 C2	I/O	Inductor connection. Drain of the internal power MOSFET. Connect to the switched side of the inductor. SW is high impedance during shutdown.
BAL	A3	O	Balancing output for dual cells super-capacitor. In steady-state operation, this output compensates for leakage current mismatch between the cells.
PGND	D1 D2		Power ground. Connect to AGND underneath IC.
AGND	A4		Analog ground.

PIN FUNCTIONS (TPS61301)

PIN		I/O	DESCRIPTION
NAME	NO.		
AVIN	E4	I	This is the input voltage pin of the device. Connect directly to the input bypass capacitor.
VOUT	A2	O	This is the output voltage pin of the converter.
LED1	E2	I	LED return input. This feedback pin regulates the LED current through the internal sense resistor by regulating the voltage across it. The regulation operates with typically 400mV (HC_SEL = L) or 400mV (HC_SEL = H) dropout voltage. Connect to the cathode of the LEDs.
LED2	E1	I	
LED3	E3	I	
FLASH_SYNC	B4	I	Flashlight strobe pulse synchronization input. FLASH_SYNC = LOW: The device is operating and regulating the LED current to the DC light current level (DCLC). FLASH_SYNC = HIGH: The device is operating and regulating the LED current to the flashlight current level (FC).
HC_SEL	B3	I	Extended high-current mode selection input. This pin must not be left floating and must be terminated. HC_SEL = LOW: LED direct drive mode. The power stage is active and the maximum LED currents are defined as 400mA/800mA/400mA (ILED1/ILED2/ILED3). HC_SEL = HIGH: Energy storage mode. In flash mode, the power stage is either active with reduced current capability or disabled. The maximum LED current is defined as 925mA/1850mA/925mA (ILED1/ILED2/ILED3).
SCL	B2	I	Serial interface clock line. This pin must not be left floating and must be terminated.
SDA	B1	I/O	Serial interface address/data line. This pin must not be left floating and must be terminated.
GPIO/PG	D4	I/O	This pin can either be configured as a general purpose input/output pin (GPIO) or either as an open-drain or a push-pull output to signal when the converters output voltage is within the regulation limits (PG). Per default, the pin is configured as an open-drain power-good output.
ENVM	C4	I	Enable pin for voltage mode converter. Pulling this pin high forces the device into voltage regulation mode (V _{OUT} is preset to a fixed value, 4.95V).

DETAILED DESCRIPTION

OPERATION

The TPS6130x family employs a 2MHz fixed on-time, PWM current-mode converter to generate the output voltage required to drive up to three high power LEDs in parallel. The device integrates a power stage based on an NMOS switch and a synchronous PMOS rectifier. The device also implements a set of linear low-side current regulators to control the LED current when the battery voltage is higher than the diode forward voltage.

A special circuit is applied to disconnect the load from the battery during shutdown of the converter. In conventional synchronous rectifier circuits, the back-gate diode of the high-side PMOS is forward biased in shutdown and allows current flowing from the battery to the output. This device however uses a special circuit which takes the cathode of the back-gate diode of the high-side PMOS and disconnects it from the source when the regulator is in shutdown (HC_SEL = L).

The TPS6130x device cannot only operate as a regulated current source but also as a standard voltage boost regulator featuring power-save mode for improved efficiency at light load. The voltage mode operation can be activated either by a software command or by means of a hardware signal (ENVM). This additional operating mode can be useful to properly synchronize the converter when supplying other high power consuming devices in the system (e.g. hands-free audio power amplifier...) or any other component requiring a supply voltage higher than the battery voltage.

The TPS6130x device also supports storage capacitor on its output (so called energy storage mode). In this operating mode (HC_SEL = H), the inductive power stage is used to charge-up the super-capacitor to a user selectable value. Once the charge-up is complete, the LEDs can be fired up to 1025mA (LED1 and LED3) and 2050mA (LED2) without causing a battery overload.

In general, a boost converter only regulates output voltages which are higher than the input voltage. This device operates differently. For example, in the voltage mode operation the device is capable to regulate 4.2V at the output from a battery voltage pulsing as high 5.5V. To control these applications properly, a down conversion mode is implemented.

If the input voltage reaches or exceeds the output voltage, the converter changes to a down conversion mode. In this mode, the control circuit changes the behavior of the rectifying PMOS. It sets the voltage drop across the PMOS as high as needed to regulate the output voltage. This means the power losses in the converter increase. This has to be taken into account for thermal consideration.

In direct drive mode (HC_SEL = L), the power stage is capable of supplying a maximum total current of roughly 1300 to 1500mA. The TPS61300 provides three constant current inputs, capable of sinking up to 400mA (LED1 and LED3) and 800mA (LED2) in flashlight mode.

The TPS6130x integrates an I²C compatible interface allowing transfers up to 3.4Mbits/s. This communication interface can be used to set the operating mode (shutdown, constant output current mode vs. constant output voltage mode), to control the brightness of the external LED (DC light and flashlight modes), to adjust the output voltage (between 3.825V and 5.7V in 125mV steps) or to program the safety timer for instance. For more details, refer to the I²C register description section.

In the TPS6130x device, the DC light and flash can be controlled either by the I²C interface or by the means of hardware control signals (ENDCL and FLASH_SYNC). To simplify flashlight synchronization with the camera module, the device offers a FLASH_SYNC strobe input pin to turn, with zero latency, the LED current from DC light to flashlight.

The maximum duration of the flashlight pulse can be limited by means of an internal user programmable safety timer (STIM). To avoid the LEDs to be kept accidentally on in DC light mode by software control, the device implements a 11.2s watchdog timer.

DOWN MODE IN VOLTAGE REGULATION MODE

In general, a boost converter only regulates output voltages which are higher than the input voltage. The featured devices come with the ability to regulate 4.2 V at the output with an input voltage being as high as 5.5V. To control these applications properly, a down conversion mode is implemented.

In voltage regulation mode, if the input voltage reaches or exceeds the output voltage, the converter changes to the down-conversion mode. In this mode, the control circuit changes the behavior of the rectifying PMOS. It sets the voltage drop across the PMOS as high as needed to regulate the output voltage. This means the power losses in the converter increase. This has to be taken into account for thermal consideration. The down conversion mode is automatically turned-off as soon as the input voltage falls about 200mV below the output voltage.

For proper operation in down conversion mode the output voltage should not be programmed higher than ca. 5.3V. Care should be taken not to violate the absolute maximum ratings at the SW pins.

The TPS6130x device uses a control architecture that allows to “recycle” excessive energy that might be stored in the output capacitor. By reversing the operation of the boost power stage, the converter is capable of transferring energy from its output back into the input source.

In high-current mode (HC_SEL = 1), this feature becomes useful to dynamically adjust the output voltage (V_{OUT}) depending on the operating conditions (e.g. +4.95V constant output voltage to support audio applications or variable storage capacitor pre-charge voltage, refer to “storage capacitor pre-charge voltage calibration” section).

Notice that this reverse operating mode can only perform within an output voltage range higher than the input supply. For example, if the storage capacitor is initially pre-charged to 4.95V, the input voltage is around 4.1V and the target output voltage is set to 3.825V, the converter will only be able to lower the output node down to the input level.

LED HIGH-CURRENT REGULATORS, UNUSED INPUTS

The TPS6130x device utilizes LED forward voltage sensing circuitry on LED1-3 pins to optimize the power stage boost ratio for maximum efficiency. Due to the nature of the sensing circuitry, it is not recommended to leave any of the LED1-3 pins unused if the operation has been selected via ENLED[3:1] bits. Leaving LED1-3 pins unconnected, whilst the respective ENLEDx bits have been set, will force the control loop into high gain and eventually trip the output over-voltage protection.

The LED1-3 inputs may be connected together to drive one or two LEDs at higher currents. Connecting the current sink inputs in parallel does not affect the internal operation of the TPS6130x. For best operation, it is recommended to disabled the LED inputs that are not used (refer to ENLED[3:1] bits description).

To achieve smooth LED current waveforms, the TPS61300 device actively controls the LED current ramp-up/down sequence.

Table 1. LED Current Ramp-Up/Down Control vs Operating Mode

	DIRECT DRIVE MODE (HC_SEL = 0)	HIGH-CURRENT MODE (HC_SEL = 1)
LED CURRENT RAMP-UP	$I_{STEP} = 25 \text{ mA}$	$I_{STEP} = 56.25 \text{ mA}$
	$t_{RISE} = 12 \text{ } \mu\text{s}$	$t_{RISE} = 0.5 \text{ } \mu\text{s}$
	Slew-rate $\neq 2.08 \text{ mA}/\mu\text{s}$	Slew-rate $\neq 112.5 \text{ mA}/\mu\text{s}$
LED CURRENT RAMP-DOWN	$I_{STEP} = 25 \text{ mA}$	$I_{STEP} = 56.25 \text{ mA}$
	$t_{FALL} = 0.5 \text{ } \mu\text{s}$	$t_{FALL} = 0.5 \text{ } \mu\text{s}$
	Slew-rate $\neq 50 \text{ mA}/\mu\text{s}$	Slew-rate $\neq 112.5 \text{ mA}/\mu\text{s}$

Figure 57. LED Current Slew-Rate Control

In high-current mode ($HC_SEL = 1$), the LED current settings are defined as a fixed ratio ($\times 2.25$) versus the direct drive mode values ($HC_SEL = L$).

POWER-SAVE MODE OPERATION, EFFICIENCY

The TPS6130x device integrates a power save mode to improve efficiency at light load. In power save mode the converter only operates when the output voltage trips below a set threshold voltage. It ramps up the output voltage with one or several pulses and goes again into power save mode once the output voltage exceeds the set threshold voltage.

Figure 58. Operation in PFM Mode and Transfer to PWM Mode

The power save mode can be enabled and disabled via the ENPSM bit. In down conversion mode, power save mode is always active and the device cannot be forced into fixed frequency operation at light loads.

The LED sense voltage has a direct effect on the converter's efficiency. Because the voltage across the low-side current regulator does not contribute to the output power (LED brightness), the lower the sense voltage the higher the efficiency will be.

In direct drive mode ($HC_SEL = L$), the energy is being directly transferred from the battery to the LEDs. The integrated current control loop automatically selects the minimum boosting ratio to maintain regulation based on the LED forward voltage and current requirements. The low-side current regulators will be dropping the voltage difference between the input voltage and the LEDs forward voltage ($V_{F(LED)} < V_{IN}$). When running in boost mode ($V_{F(LED)} > V_{IN}$), the voltage present at the LED1-3 pins of the low-side current regulators will be typically 400mV leading to high power conversion efficiency. Depending on the input voltage and the LEDs forward voltage characteristic the converter will show efficiency in the range of about 75% to 90%.

In high-current mode ($HC_SEL = H$), the device is only supplying a limited amount of energy directly from the battery (i.e. DC light, contribution to flash current or voltage regulation mode). During a flash strobe, the bulk of the energy supplied to the LEDs is provided by the reservoir capacitor. The low-side current regulators will be typically operating with 400mV headroom voltage. This means the power losses in the device increase and special care should be taken for thermal considerations.

MODE OF OPERATION: DC LIGHT AND FLASHLIGHT

Operation is understood best by referring to the timer block diagram. Depending on the settings of MODE_CTRL[1:0] bits the device can enter 4 different operating modes. The below section details the converter's operation for ENV_M = 0.

- MODE_CTRL[1:0] = 00: The device is in shutdown mode.
- MODE_CTRL[1:0] = 01: The device is regulating the LED current to the DC light current level (DCLC bits) regardless of the FLASH_SYNC input and START_FLASH/TIMER (SFT) bit. To avoid device shutdown by DC light safety timeout, MODE_CTRL[1:0] needs to be refreshed within less than 11.2s.
- MODE_CTRL[1:0] = 11: The device is regulating a constant output voltage according to OV[3:0] bits settings. The low-side LED1-3 current sinks are disabled and the LEDs are disconnected from the output. In this operating mode, the safety timer is disabled.
- MODE_CTRL[1:0] = 10: The flashlight pulse can be either trigger by a hardware signal (FLASH_SYNC) or by a software bit (SFT). LED strobe pulse follows FLASH_SYNC.

FLASH STROBE IS LEVEL SENSITIVE (STT = 0): LED STROBE FOLLOWS FLASH_SYNC INPUT

FLASH_SYNC and (SFT) = 0: LED operation is set to the DC light current level. To avoid device shutdown by DC light safety timeout, MODE_CTRL[1:0] needs to be refreshed within less than 11.2s.

FLASH_SYNC or (SFT) = 1: The LED is driven at the flashlight current level and the safety timer is running. The maximum duration of the flashlight pulse is defined in the STIM[2:0] register.

Figure 59. DC Light Operation

Figure 60. Synchronized Flashlight Strobe

Figure 61. Level Sensitive Safety Timer (Timeout)

Figure 62. Level Sensitive Safety Timer (Normal Operation + Timeout)

The safety timer is started by:

- a rising edge of FLASH_SYNC signal.
- a rising edge of START_FLASH/TIMER (SFT) bit.

The safety timer is stopped by:

- a low level of FLASH_SYNC signal or START_FLASH/TIMER (SFT) bit.
- a timeout signal (TO).

START-FLASH/TIMER (SFT) bit is being reset by the timeout (TO) signal.

FLASH STROBE IS LEADING EDGE SENSITIVE (STT = 1): ONE-SHOT LED STROBE

When FLASH_SYNC and START_FLASH/TIMER (SFT) are both low the LED operation is set to the DC Light current level. To avoid device shutdown by DC light safety timeout, MODE_CTRL[1:0] needs to be refreshed within less than 11.2s.

The duration of the flashlight pulse is defined in the STIM register. The flashlight strobe is started by:

- a rising edge of START_FLASH/TIMER (SFT) bit.
- a rising edge of FLASH_SYNC signal.

Once running, the timer ignores all kind of triggering signal and only stops after a timeout (TO). START-FLASH/TIMER (SFT) bit is being reset by the timeout (TO) signal.

Figure 63. Edge Sensitive Timer (Single Trigger Event)

Figure 64. Edge Sensitive Timer (Single Trigger Event)

Figure 65. Edge Sensitive Timer (Multiple Trigger Events)

SAFETY TIMER ACCURACY

The LED strobe timer uses the internal oscillator as reference clock. As a matter of fact, the timer execution speed (refer to STIM[2:0]) scales according to the reference clock accuracy.

OSCILLATOR FREQUENCY	SAFETY TIMER DURATION
Minimum	Maximum = Typical $\times (1 + f_{ACC})^{(1)}$
Typical	Typical $^{(2)}$
Maximum	Minimum = Typical $\times (1 - f_{ACC})^{(1)}$

(1) Refer to REGISTER3, STIM[2:0] definition.

(2) Refer to the Electrical Characteristics table.

CURRENT LIMIT OPERATION

The current limit circuit employs a valley current sensing scheme. Current limit detection occurs during the off time through sensing of the voltage drop across the synchronous rectifier. The detection threshold is user selectable via the ILIM bit. The ILIM bit can only be set before the device enters operation (i.e., initial shutdown state).

Figure 66 illustrates the inductor and rectifier current waveforms during current limit operation. The output current, I_{OUT} , is the average of the rectifier ripple current waveform. When the load current is increased such that the lower peak is above the current limit threshold, the off time is lengthened to allow the current to decrease to this threshold before the next on-time begins (so called frequency fold-back mechanism).

Both the output voltage and the switching frequency are reduced as the power stage of the device operates in a constant current mode. The maximum continuous output current ($I_{OUT(CL)}$), before entering current limit operation, can be defined as:

$$I_{OUT(CL)} = (1 - D) \times (I_{VALLEY} + \frac{1}{2} \Delta I_L) \text{ with } \Delta I_L = \frac{V_{IN}}{L} \times \frac{D}{f} \text{ and } D \approx \frac{V_{OUT} - V_{IN}}{V_{OUT}} \quad (1)$$

The TPS6130x device also provides a negative current limit (c.a. 300mA) to prevent an excessive reverse inductor current when the power stage sinks current from the output (i.e., storage capacitor) in the forced continuous conduction mode.

Figure 66. Inductor/Rectifier Currents in Current Limit Operation

To minimize the requirements on the energy storage capacitor present at the output of the driver ($HC_SEL = 1$), the TPS6130x device can contribute to a larger extent in supporting directly the high-current LED flash strobe. In fact, the device can dynamically adjust its current limit setting according to the Tx-MASK input.

Table 2. Inductor Current Limit Operation vs HC_SEL/Tx-MASK Inputs

CURRENT LIMIT SETTING	ILIM BIT	HC_SEL INPUT	Tx-MASK INPUT
1250 mA	Low	Low	Low
1750 mA	High	Low	Low
1250 mA	Low	High	Low
1750 mA	High	High	Low
1250 mA	Low	Low	High
1750 mA	High	Low	High
250 mA	Low	High	High
500 mA	High	High	High

LED FAILURE MODES AND OVER-VOLTAGE PROTECTION

If a high-power LED fails as a short circuit, the low-side current regulator will limit the maximum output current and the HIGH-POWER LED FAILURE (HPLF) flag will be set.

If a high-power LED fails as an open circuit, the control loop will initially attempt to regulate off of its low-side current regulator feedback signal. This will drive V_{OUT} higher. As the open circuited LED will never accept its programmed current, V_{OUT} must be voltage-limited by means of a secondary control loop.

The TPS6130x device limits V_{OUT} according to the over-voltage protection settings (refer to OVP specification). In this failure mode, V_{OUT} is either limited to 4.65V (typ.) or 6.0V (typ.) and the HIGH-POWER LED FAILURE (HPLF) flag is set.

OVP THRESHOLD	OPERATING CONDITIONS
4.65 V typ	HC_SEL = L and 0000 ≤ OV[3:0] ≤ 0100
6.0 V typ	HC_SEL = H or 0101 ≤ OV[3:0] ≤ 1111

Refer to the section “LED High-Current Regulators, Unused inputs” for additional information.

Figure 67. Over-Voltage Protection Operation (4.65V typ)

HARDWARE VOLTAGE MODE SELECTION

The TPS6130x device integrates a logic input (ENV_M) and/or a software control bit (ENV_M bit) that can be used to force the converter to run in voltage mode regulation. Pulling the ENV_M pin high forces the device into voltage regulation mode (V_{OUT} is preset to a fixed value, 4.95V). This additional operating mode can be useful to supply other high power consuming devices in the system (e.g., hands-free audio power amplifier...) or any other component requiring a regulated supply voltage higher or lower than the battery voltage.

Table 3 gives an overview of the different mode of operation.

Table 3. Operating Mode Description

INTERNAL REGISTER SETTINGS MODE_CTRL[1:0]	ENVM BIT	OPERATING MODES
00	0	The converter is in shutdown mode and the load is disconnected from the battery.
01	0	LEDs are turned-on for DC light operation (i.e. movie-light). The converter is operating in the current regulation mode (CM). The output voltage is controlled by the forward voltage characteristic of the LED. The energy is being directly transferred from the battery to the output. The integrated current control loop automatically selects the minimum boosting ratio to maintain regulation based on the LED forward voltage and current requirements. When running in linear mode ($V_{F(LED)} < V_{IN}$), the dc/dc power stage featuring valley-current limit is not active permitting relatively large currents to circulate from the input to the output of the device.
10	0	The converter is operating in the current regulation mode (CM). The output voltage is controlled by the forward voltage characteristic of the LED. LEDs are ready for flashlight operation and DC light operation is supported directly from the battery. The integrated current control loop automatically selects the minimum boosting ratio to maintain regulation based on the LED forward voltage and current requirements. When running in linear mode ($V_{F(LED)} < V_{IN}$), the dc/dc power stage featuring valley-current limit is not active permitting relatively large currents to circulate from the input to the output of the device.
		In high-current mode (HC_SEL = H), the energy is supplied by the output reservoir capacitor and the inductive power stage is turned-off for the flash strobe period of time.
11	0	LEDs are turned-off and the converter is operating in the voltage regulation mode (VM). The output voltage is set via the register OV[3:0].
00	1	LEDs are turned-off and the converter is operating in the voltage regulation mode (VM). The output voltage is set via the register OV[3:0].
01	1	The converter is operating in the voltage regulation mode (VM) and it's output voltage is set via the register OV[3:0]. The LEDs are turned-on for DC light operation and the energy is being directly transferred from the battery to the output. The LED currents are regulated by the means of the low-side current sinks.
10	1	The converter is operating in the voltage regulation mode (VM) and it's output voltage is set via the register OV[3:0]. The LED currents are regulated by the means of the low-side current sinks. The LEDs are ready for flashlight operation. In direct drive mode (HC_SEL = L), the energy is being directly transferred from the battery to the output. In high-current mode (HC_SEL = H), the energy is largely supplied by the output reservoir capacitor. The inductive power stage is turned-on to support DC light operation and to contribute the flash strobe itself.
11	1	LEDs are turned-off and the converter is operating in the voltage regulation mode (VM). The output voltage is set via the register OV[3:0].

START-UP SEQUENCE

To avoid high inrush current during start-up, special care is taken to control the inrush current. When the device enables, the internal startup cycle starts with the first step, the pre-charge phase.

During pre-charge, the rectifying switch is turned on until the output capacitor is either charged to a value close to the input voltage or ca. 3.3V, whichever occurs first. The rectifying switch is current limited during that phase. The current limit increases with decreasing input to output voltage difference. This circuit also limits the output current under short-circuit conditions at the output. Figure 68 shows the typical pre-charge current vs. input minus the output voltage for a specific input voltage.

Figure 68. Typical DC Pre-charge and Short-Circuit Current

In direct drive mode ($\text{HC_SEL} = \text{L}$, TPS6130x), after having pre-charged the output capacitor, the device starts-up switching and increases its current limit in three steps of typically 250mA, 500mA and full current limit (ILIM setting). The current limit transitions from the first to the second step occurs after a milli-second operation. Full current limit operation is set once the output voltage has reached its regulation limits. In this mode, the active balancing circuit is disabled.

In high-current mode ($\text{HC_SEL} = \text{H}$), the pre-charge voltage of the storage capacitor is depending on the input voltage and operating mode (i.e., voltage regulation vs. current regulation mode). In case the device is set for exclusive current regulation operation (i.e., $\text{MODE_CTRL}[1:0] = 01$ or 10 and $\text{ENVN} = 0$), the output capacitor pre-charge voltage will be close to the input voltage. Under all other operating conditions, the pre-charge voltage will either be close to the input voltage or to approximately 3.3V, whichever is lower.

After having pre-charged the storage capacitor, the device starts-up switching. During down-mode operation, the inductor valley current is actively limited either to 250mA or 500mA (refer to ILIM setting). As the device enters boost mode operation, the current limit transitions to its full capability (refer to ILIM setting and Tx-MASK input logic state). As a consequence, the output voltage ramps-up linearly and the start-up time needed to reach the programmed output voltage (refer to $\text{OV}[3:0]$ bits) will mainly depend on the super-capacitor value and load current. In this mode, the active balancing circuit is enabled.

POWER GOOD (FLASH READY)

The TPS6130x integrates a power good circuitry that is activated when the device is operating in voltage regulation mode (MODE_CTRL[1:0] = 11 or ENVM = 1). In shutdown mode (MODE_CTRL[1:0] = 00, ENDCL = 0 and ENVM = 0), the GPIO/PG pin state is defined as following:

GPIOTYPE	GPIO/PG SHUTDOWN STATE
0	Reset/pulled to ground
1	Open-drain

Depending on the GPIO/PG output stage type selection (i.e., push-pull or open-drain), the polarity of the power-good output signal (PG) can be inverted or not. The power-good software bit and hardware signal polarity is defined as following:

GPIOTYPE	PG BIT	GPIO/PG OUTPUT PORT	COMMENTS
0: push-pull output	0	0	Output is active high signal polarity
	1	1	
1: open-drain output	0	Open-drain	Output is active low signal polarity
	1	Low	

The power good signal is valid when the output voltage is within -1.5% and $+2.5\%$ of its nominal value. Conversely, it is asserted low when the voltage mode operation gets suspended (MODE_CTRL[1:0] $\neq$ 11 and ENVM = 0).

Figure 69. Power Good Operation (DIR = 1, GPIOTYPE = 1)

The TPS6130x device uses a control architecture that allows to “recycle” excessive energy that might be stored in the output capacitor. By reversing the operation of the boost power stage, the converter is capable of transferring energy from its output back into the input source. In this case, the power good signal is de-asserted whilst the output voltage is decreasing towards its target value (i.e., the closest fit voltage the converter can support, refer to the section “Down-Mode in Voltage Regulation Mode” for additional information).

LED TEMPERATURE MONITORING (TPS61305, TPS61305A, TPS61306)

The TPS61305, TPS61305A and TPS61306 devices monitor the LED temperature by measuring the voltage between the TS and AGND pins. An internal current source provides the bias (c.a. 24 μ A) for a negative-temperature coefficient resistor (NTC), and the TS pin voltage is compared to internal thresholds (1.05V and 0.345V) to protect the LEDs against overheating.

The temperature monitoring related blocks are always active in DC light or flashlight modes. In voltage mode operation (MODE_CTRL[1:0] = 11), the device only activates the TS input when the ENTS bit is set to high. In shutdown mode, the LED temperature supervision is disabled and the quiescent current of the device is dramatically reduced.

The LEDWARN and LEDHOT bits reflect the LED temperature. The LEDWARN bit is set when the voltage seen at the TS pin is lower than 1.05V. This threshold corresponds to an LED warning temperature value, the device operation is still permitted.

While regulating LED current (i.e., DC light or flashlight modes), the LEDHOT bit is latched when the voltage seen at the TS pin is lower than 0.345V. This threshold corresponds to an excessive LED temperature value, the device operation is immediately suspended (MODE_CTRL[1:0] bits are reset and HOTDIE[1:0] bits are set).

HOT DIE DETECTOR

The hot die detector monitors the junction temperature but does not shutdown the device. It provides an early warning to the camera engine to avoid excessive power dissipation thus preventing from thermal shutdown during the next high-power flash strobe.

The hot die detector (HOTDIE[1:0] bits) reflects the instantaneous junction temperature and is always enabled excepted when the device is in shutdown mode (MODE_CTRL[1:0] = 00, ENVM = 0 and ENDCL = 0).

NRESET INPUT: HARDWARE ENABLE / DISABLE

Some devices out of the TPS6130x family feature a hardware reset pin (NRESET). This reset pin allows the device to be disabled by an external controller without requiring an I²C write command. Under normal operation, the NRESET pin should be held high to prevent an unwanted reset. When the NRESET is driven low, the I²C control interface and all internal control registers are reset to the default states and the part enters shutdown mode.

ENDCL INPUT: DC LIGHT HARDWARE CONTROL

Some devices out of the TPS6130x family feature a dedicated DC light control input (ENDCL). This logic input can be used to turn-on the LEDs for DC light operation. This hardware control pin can be useful to control the torch light functionality from a separate engine (e.g., base-band). In this mode of operation, the DC light safety timer is not activated.

The ENDCL input is only active when the device is programmed into shutdown (MODE_CTRL[1:0] = 00) or into voltage regulation mode (MODE_CTRL[1:0] = 11 or ENVM = 1) and the indicator control is turned-off (INDC[3:0] = 0000). LED1-3 inputs are controlled according to ENLED[3:1] bit settings.

FLASHLIGHT BLANKING (Tx-MASK)

In direct drive mode ($HC_SEL = 0$), the Tx-MASK input signal can be used to disable the flashlight operation, e.g., during a RF PA transmission pulse. This blanking function turns the LED from flashlight to DC light thereby reducing almost instantaneously the peak current loading from the battery. The Tx-MASK function has no influence on the safety timer duration.

Figure 70. Synchronized Flashlight With Blanking Periods

In high-current mode ($HC_SEL = 1$), the Tx-MASK input pin is also used to dynamically adjust the device's current limit setting (i.e. controls the maximum current drawn from the input source). Refer to the section "Current Limit Operation" for additional information.

UNDERVOLTAGE LOCKOUT

The under-voltage lockout circuit prevents the device from mis-operation at low input voltages. It prevents the converter from turning on the switch-MOSFET, or rectifier-MOSFET for battery voltages below 2.3V. The I2C compatible interface is fully functional down to 2.1V input voltage.

SHUTDOWN

MODE_CTRL[1:0] bits low force the device into shutdown. The shutdown state can only be entered when the voltage regulation and DC light modes are both turned-off ($ENVN = 0$ and $ENDCL = 0$).

In direct drive mode ($HC_SEL = L$), the regulator stops switching, the high-side PMOS disconnects the load from the input and the LEDx pins are high impedance thus eliminating any DC conduction path. The TPS6130x device actively discharges the output capacitor when it turns off.

The integrated discharge resistor has a typical resistance of 2k Ω equally split-off between VOUT to BAL and BAL to GND outputs. The required time to discharge the output capacitor at V_{OUT} depends on load current and the effective output capacitance. The active balancing circuit is disabled and the device consumes only a shutdown current of 1 μ A (typ).

In high-current mode ($HC_SEL = H$), the device maintains its output biased at the input voltage level. In this mode, the synchronous rectifier is current limited (i.e. pre-charge current) allowing external load (e.g. audio amplifier) to be powered with a restricted supply. The active balancing circuit is enabled and the device consumes only a standby current of 5 μ A (typ).

THERMAL SHUTDOWN

As soon as the junction temperature, T_J , exceeds 160°C typical, the device goes into thermal shutdown. In this mode, the power stage and the low-side current regulators are turned-off, the HOTDIE[1:0] bits are set and can only be reset by a readout.

In the voltage mode operation ($\text{MODE_CTRL}[1:0] = 11$ or $\text{ENVM} = 1$), the device continues its operation when the junction temperature falls below 140°C typ. again. In the current regulation mode (i.e., DC light or flashlight modes) the device operation is suspended.

STORAGE CAPACITOR ACTIVE CELL BALANCING

A fully charged super-capacitor will typically have leakage current of under $1\mu\text{A}$. The TPS6130x device integrates an active balancing feature to cut the total leakage current from the super-capacitor and balance circuit to less than $1.7\mu\text{A}$ typ.

The device integrates a window comparator monitoring the tap point of the multi-cell super-capacitor. The balancing output (BAL) is substantially half the actual output voltage (V_{OUT}). If the internal leakage current in one of the capacitors is larger than that in the other, then the voltage at their junction will tend to change in such a way that the voltage on the capacitor with the larger (or largest) leakage current will reduce.

When this happens, a current will begin to flow from the BAL output in such a direction as to reduce the amount by which the voltage changes. The current that will flow after a long period of steady-state conditions will be approximately equal to the difference between the leakage currents of the pair of capacitors which is being balanced by the circuit. The output resistance of the balancing circuit (c.a. 250Ω) determines how quickly an imbalance will be corrected.

RED LIGHT PRIVACY INDICATOR

The TPS6130x device provides a high-side linear constant current source to drive low VF LEDs. The LED current is directly regulated off the battery and can be controlled via the INDC[3:0] bits. Operation is understood best by referring to the [Figure 71](#) and [Figure 72](#).

Figure 71. RED Light Indicator, Configuration 1

Figure 72. RED Light Indicator, Configuration 2

The device can provide a path to allow for reverse biasing of white LEDs (refer to [Figure 72](#)). To do so, the output of the converter (VOUT) is pulled to ground thus allowing a reverse current to flow. This mode of operation is only possible when the converter's power stage is in shutdown (MODE_CTRL[1:0] = 00, ENVN = 0, ENDCL = 0 and HC_SEL = 0).

WHITE LED PRIVACY INDICATOR

The TPS6130x device features white LED drive capability at very low light intensity. To generate a reduced LED average current, the device employs a 122Hz fixed frequency PWM modulation scheme. Operation is understood best by referring to the timer block diagram.

The DC light current is modulated with a duty cycle defined by the INDC[3:0] bits. The low light dimming mode can only be activated in the software controlled DC light only mode (MODE_CTRL[1:0] = 01, ENVN = X, ENDCL = 0) and applies to the LEDs selected via ENLED[3:1] bits. In this mode, the DC light safety timeout feature is disabled.

Figure 73. PWM Dimming Principle

STORAGE CAPACITOR, PRE-CHARGE VOLTAGE CALIBRATION

High-power LEDs tend to exhibit a wide forward voltage distribution. The TPS6130x device integrates a self-calibration procedure that can be used to determine the optimum super-capacitor pre-charge voltage based on the actual worst case LED forward voltage and ESR of the storage capacitor. This calibration procedure is meant to start-off at a min. output voltage and can be initiated by setting the SELFCAL bit (preferably with `MODE_CTRL[1:0] = 00`, `ENVM = 0`, `ENDCL = 0`).

The calibration procedure monitors the sense voltage across the low-side current regulators (according to `ENLED[3:1]` bits setting) and registers the worst case LED (i.e. the LED featuring the largest forward voltage). The TPS6130x device automatically sweeps through its output voltage range and performs a short duration flash strobe for each step (refer to `FC13[1:0]` and `FC2[2:0]` bits settings).

In direct drive mode (`HC_SEL = L`), the energy is being directly transferred from the battery to the LEDs. In high-current mode (`HC_SEL = H`), the energy is supplied exclusively by the output reservoir capacitor and the inductive power stage is turned-off for the flash strobe period of time.

The sequence is stopped as soon as the device detects that each of the low-side current regulators have enough headroom voltage (i.e. 400mV typ.). The device returns the according output voltage in the register `OV[3:0]` and sets the SELFCAL bit. This bit is only being reset at the (re-)start of a calibration cycle. In other words, when SELFCAL is asserted the output voltage register (`OV[3:0]`) returns the result of the last calibration sequence.

Figure 74. LED Forward Voltage Self-Calibration Principle

STORAGE CAPACITOR, ADAPTIVE PRE-CHARGE VOLTAGE

In high-power LED camera flash applications, the storage capacitor is supposed to be charged to an optimum voltage level in order to:

- Maintain sufficient headroom voltage across the LED current regulators for the entire strobe time.
- Minimize the power dissipation in the device.

High-power LEDs tend to exhibit large dynamic forward voltage variation relating to own self-heating effects. In addition, the energy storage capacitor (i.e., Electrochemical Double-Layer Capacitor or Super-Capacitor) also shows a relatively large effective capacitance and ESR spread. The main factors contributing to these variations are:

- Flash strobe duration
- Temperature
- Ageing effects

In practice, it normally becomes very challenging to compensate for all these variations and a worst-case design would presumably be too pessimistic. As a consequence, designers would have to give-up on the benefits coming along with the “Storage Capacitor, Pre-Charge Voltage Calibration” approach.

The TPS6130x device offers the possibility of controlling the storage capacitor pre-charge voltage in a closed-loop manner. The principle is to dynamically adjust the initial pre-voltage to the minimum value, as required for the particular components characteristic and operating conditions.

The reference criteria used to evaluate proper operation is the headroom voltage across the LED current regulators. In case of a critical headroom voltage (V_{LED1-3}) at the end of a flash strobe (i.e., n cycle), the pre-charge voltage should be increased prior to the next capture sequence (i.e., $n+1$ cycle).

Figure 75. Storage Capacitor, Simple Adaptive Pre-Charge Voltage

SERIAL INTERFACE DESCRIPTION

I²C™ is a 2-wire serial interface developed by Philips Semiconductor, now NXP Semiconductors (see I2C-Bus Specification, Version 2.1, January 2000). The bus consists of a data line (SDA) and a clock line (SCL) with pull-up structures. When the bus is *idle*, both SDA and SCL lines are pulled high. All the I²C compatible devices connect to the I²C bus through open drain I/O pins, SDA and SCL. A *master* device, usually a microcontroller or a digital signal processor, controls the bus. The master is responsible for generating the SCL signal and device addresses. The master also generates specific conditions that indicate the START and STOP of data transfer. A *slave* device receives and/or transmits data on the bus under control of the master device.

The TPS6130x device works as a *slave* and supports the following data transfer *modes*, as defined in the I²C-Bus Specification: standard mode (100 kbps) and fast mode (400 kbps), and high-speed mode (3.4 Mbps). The interface adds flexibility to the power supply solution, enabling most functions to be programmed to new values depending on the instantaneous application requirements. Register contents remain intact as long as supply voltage remains above 2.1V.

The data transfer protocol for standard and fast modes is exactly the same, therefore they are referred to as F/S-mode in this document. The protocol for high-speed mode is different from F/S-mode, and it is referred to as HS-mode. The TPS6130x device supports 7-bit addressing; 10-bit addressing and general call address are not supported. The device 7bit address is defined as '011 0011'.

F/S-MODE PROTOCOL

The master initiates data transfer by generating a start condition. The start condition is when a high-to-low transition occurs on the SDA line while SCL is high, as shown in Figure 76. All I²C-compatible devices should recognize a start condition.

Figure 76. START and STOP Conditions

The master then generates the SCL pulses, and transmits the 7-bit address and the read/write direction bit R/W on the SDA line. During all transmissions, the master ensures that data is valid. A valid data condition requires the SDA line to be stable during the entire high period of the clock pulse (see Figure 77). All devices recognize the address sent by the master and compare it to their internal fixed addresses. Only the slave device with a matching address generates an acknowledge (see Figure 78) by pulling the SDA line low during the entire high period of the ninth SCL cycle. Upon detecting this acknowledge, the master knows that communication link with a slave has been established.

Figure 77. Bit Transfer on the Serial Interface

The master generates further SCL cycles to either transmit data to the slave (R/W bit 1) or receive data from the slave (R/W bit 0). In either case, the receiver needs to acknowledge the data sent by the transmitter. So an acknowledge signal can either be generated by the master or by the slave, depending on which one is the receiver. 9-bit valid data sequences consisting of 8-bit data and 1-bit acknowledge can continue as long as necessary.

To signal the end of the data transfer, the master generates a stop condition by pulling the SDA line from low to high while the SCL line is high (see Figure 76). This releases the bus and stops the communication link with the addressed slave. All I²C compatible devices must recognize the stop condition. Upon the receipt of a stop condition, all devices know that the bus is released, and they wait for a start condition followed by a matching address.

Attempting to read data from register addresses not listed in this section will result in 00h being read out.

Figure 78. Acknowledge on the I²C Bus

Figure 79. Bus Protocol

HS-MODE PROTOCOL

The master generates a start condition followed by a valid serial byte containing HS master code 00001XXX. This transmission is made in F/S-mode at no more than 400 Kbps. No device is allowed to acknowledge the HS master code, but all devices must recognize it and switch their internal setting to support 3.4 Mbps operation.

The master then generates a *repeated start condition* (a repeated start condition has the same timing as the start condition). After this repeated start condition, the protocol is the same as F/S-mode, except that transmission speeds up to 3.4 Mbps are allowed. A stop condition ends the HS-mode and switches all the internal settings of the slave devices to support the F/S-mode. Instead of using a stop condition, repeated start conditions should be used to secure the bus in HS-mode.

Attempting to read data from register addresses not listed in this section will result in 00h being read out.

TPS6130x I2C UPDATE SEQUENCE

The TPS6130x requires a start condition, a valid I²C address, a register address byte, and a data byte for a single update. After the receipt of each byte, TPS6130x device acknowledges by pulling the SDA line low during the high period of a single clock pulse. A valid I²C address selects the TPS6130x. TPS6130x performs an update on the falling edge of the acknowledge signal that follows the LSB byte.

Figure 80. : "Write" Data Transfer Format in F/S-Mode

Figure 81. "Read" Data Transfer Format in F/S-Mode

Figure 82. Data Transfer Format in H/S-Mode

SLAVE ADDRESS BYTE

MSB							LSB
X	X	X	X	X	X	A1	A0

The slave address byte is the first byte received following the START condition from the master device.

REGISTER ADDRESS BYTE

MSB							LSB
0	0	0	0	00	D2	D1	D0

Following the successful acknowledgement of the slave address, the bus master will send a byte to the TPS6130x, which will contain the address of the register to be accessed.

REGISTER1 DESCRIPTION (TPS61300, TPS61301)

Memory location: 0x01

Description	ENVM	MODE_CTRL[1:0]		DCLC13[1:0]		DCLC2[1:0]		
Bits	D7	D6	D5	D4	D3	D2	D1	D0
Memory type	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Default value	0	0	0	0	1	0	0	1

Bit	Description
ENVM	Enable Voltage Mode bit. 0: Normal operation. 1: Forces the device into a constant voltage source. In read mode, the ENVM bit is automatically updated to reflect the logic state of the ENVM input pin.
MODE_CTRL[1:0]	Mode Control bits. 00: Device in shutdown mode. 01: Device operates in DC light mode. 10: Device operates in DC light and flash mode. 11: Device operates as constant voltage source. To avoid device shutdown by DC light safety timeout, MODE_CTRL[1:0] bits need to be refreshed within less than 11.2s. Writing to REGISTER1[6:5] automatically updates REGISTER2[6:5].
DCLC13[1:0]	DC Light Current Control bits (LED1/3). 00: 0mA. LEDs are off, V_{OUT} set according to OV[3:0]. ^{(1) (2)} 01: 50mA 10: 75mA 11: 100mA
DCLC2[2:0]	DC Light Current Control bits (LED2). 000: 0mA. LEDs are off, V_{OUT} set according to OV[3:0]. ^{(1) (2)} 001: 50mA 010: 75mA 011: 100mA 100: 125mA 101: 150mA 110: 200mA, 350mA current level can be activated simultaneously with Tx-MASK = 1. 111: 250mA, 500mA current level can be activated simultaneously with Tx-MASK = 1.

- (1) When DCLC2[2:0] and DCLC13[1:0] are both reset, the device operates in voltage regulation mode. The output voltage is set according to OV[3:0].
- (2) To ensure a proper transition into voltage mode operation, it is recommended to disable the LEDs (i.e. ENLED[2:0] bits are reset) prior to clearing DCLC2[2:0] and DCLC13[1:0] bits.

APPLICATION INFORMATION

INDUCTOR SELECTION

A boost converter requires two main passive components for storing energy during the conversion. A boost inductor and a storage capacitor at the output are required. The TPS6130x device integrates a current limit protection circuitry. The valley current of the PMOS rectifier is sensed to limit the maximum current flowing through the synchronous rectifier and the inductor. The valley peak current limit (250mA/500mA/1250mA/1750mA) is user selectable via the I²C interface.

In order to optimize solution size the TPS6130x device has been designed to operate with inductance values between a minimum of 1.3 µH and maximum of 2.9 µH. In typical high current white LED applications a 2.2µH inductance is recommended.

The highest peak current through the inductor and the power switch depends on the output load, the input and output voltages. Estimation of the maximum average inductor current and the maximum inductor peak current can be done using [Equation 2](#) and [Equation 3](#):

$$I_L \approx I_{OUT} \times \frac{V_{OUT}}{\eta \times V_{IN}} \quad (2)$$

$$I_{L(PEAK)} = \frac{V_{IN} \times D}{2 \times f \times L} + \frac{I_{OUT}}{(1-D) \times \eta} \quad \text{with } D = \frac{V_{OUT} - V_{IN}}{V_{OUT}} \quad (3)$$

With

f = switching frequency (2MHz)

L = inductance value (2.2µH)

η = estimated efficiency (85%)

The losses in the inductor caused by magnetic hysteresis losses and copper losses are a major parameter for total circuit efficiency.

Table 4. List of Inductors

MANUFACTURER	SERIES	DIMENSIONS	ILIM SETTINGS

INPUT CAPACITOR

For good input voltage filtering low ESR ceramic capacitors are recommended. A 10-µF input capacitor is recommended to improve transient behavior of the regulator and EMI behavior of the total power supply circuit. The input capacitor should be placed as close as possible to the input pin of the converter.

OUTPUT CAPACITOR

The major parameter necessary to define the output capacitor is the maximum allowed output voltage ripple of the converter. This ripple is determined by two parameters of the capacitor, the capacitance and the ESR. It is possible to calculate the minimum capacitance needed for the defined ripple, supposing that the ESR is zero, by using [Equation 4](#):

$$C_{min} \approx \frac{I_{OUT} \times (V_{OUT} - V_{IN})}{f \times \Delta V \times V_{OUT}} \quad (4)$$

Parameter f is the switching frequency and ΔV is the maximum allowed ripple.

With a chosen ripple voltage of 10mV, a minimum capacitance of 10 μ F is needed. The total ripple is larger due to the ESR of the output capacitor. This additional component of the ripple can be calculated using [Equation 5](#):

$$\Delta V_{ESR} = I_{OUT} \times R_{ESR} \quad (5)$$

The total ripple is the sum of the ripple caused by the capacitance and the ripple caused by the ESR of the capacitor. Additional ripple is caused by load transients. This means that the output capacitor has to completely supply the load during the charging phase of the inductor. A reasonable value of the output capacitance depends on the speed of the load transients and the load current during the load change.

For the standard current white LED application ($HC_SEL = 0$, TPS6130x), a minimum of 3 μ F effective output capacitance is usually required when operating with 2.2 μ H (typ) inductors. For solution size reasons, this is usually one or more X5R/X7R ceramic capacitors.

Depending on the material, size and therefore margin to the rated voltage of the used output capacitor, degradation on the effective capacitance can be observed. This loss of capacitance is related to the DC bias voltage applied. It is therefore always recommended to check that the selected capacitors are showing enough effective capacitance under real operating conditions.

To support high-current camera flash application ($HC_SEL = 1$), the converter is designed to work with a low voltage super-capacitor on the output to take advantage of the benefits they offer. A low-voltage super-capacitor in the 0.1F to 1.5F range, and with ESR larger than 40m Ω , is suitable in the TPS6130x application circuit. For this device the output capacitor should be connected between the VOUT pin and a good ground connection.

NTC SELECTION (TPS61305, TPS61305A, TPS61306)

The TPS61305/305A/306 requires a negative thermistor (NTC) for sensing the LED temperature. Once the temperature monitoring feature is activated, a regulated bias current (c.a. 24µA) will be driven out of the TS port and produce a voltage across the thermistor.

If the temperature of the NTC-thermistor rises due to the heat dissipated by the LED, the voltage on the TS input pin decreases. When this voltage goes below the “warning threshold”, the LEDWARN bit in REGISTER6 is set. This flag is cleared by reading the register.

If the voltage on the TS input decreases further and falls below “hot threshold”, the LEDHOT bit in REGISTER6 is set and the device goes automatically in shutdown mode to avoid damaging the LED. This status is latched until the LEDHOT flag gets cleared by software.

The selection of the NTC-thermistor value strongly depends on the power dissipated by the LED and all components surrounding the temperature sensor and on the cooling capabilities of each specific application. With a 220kΩ (at 25°C) thermistor, the valid temperature window is set between 60°C to 90°C. The temperature window can be enlarged by adding external resistors to the TS pin application circuit. In order to ensure proper triggering of the LEDWARN and LEDHOT flags in noisy environments, the TS signal may require additional filtering capacitance.

CHECKING LOOP STABILITY

The first step of circuit and stability evaluation is to look from a steady-state perspective at the following signals:

- Switching node, SW
- Inductor current, I_L
- Output ripple voltage, $V_{OUT(AC)}$

These are the basic signals that need to be measured when evaluating a switching converter. When the switching waveform shows large duty cycle jitter or the output voltage or inductor current shows oscillations the regulation loop may be unstable. This is often a result of improper board layout and/or L-C combination.

As a next step in the evaluation of the regulation loop the load transient response needs to be tested. V_{OUT} can be monitored for settling time, overshoot or ringing that helps judge the converter's stability. Without any ringing, the loop has usually more than 45° of phase margin.

Because the damping factor of the circuitry is directly related to several resistive parameters (e.g., MOSFET $r_{DS(on)}$) that are temperature dependant, the loop stability analysis has to be done over the input voltage range, output current range, and temperature range.

LAYOUT CONSIDERATIONS

As for all switching power supplies, the layout is an important step in the design, especially at high peak currents and high switching frequencies. If the layout is not carefully done, the regulator could show stability problems as well as EMI problems. Therefore, use wide and short traces for the main current path and for the power ground tracks.

The input capacitor, output capacitor, and the inductor should be placed as close as possible to the IC. Use a common ground node for power ground and a different one for control ground to minimize the effects of ground noise. Connect these ground nodes at any place close to one of the ground pins of the IC.

To lay out the control ground, it is recommended to use short traces as well, separated from the power ground traces. This avoids ground shift problems, which can occur due to superimposition of power ground current and control ground current.

Figure 84. Suggested Layout (Top)

THERMAL INFORMATION

Implementation of integrated circuits in low-profile and fine-pitch surface-mount packages typically requires special attention to power dissipation. Many system-dependant issues such as thermal coupling, airflow, added heat sinks and convection surfaces, and the presence of other heat-generating components affect the power-dissipation limits of a given component.

Three basic approaches for enhancing thermal performance are listed below:

- Improving the power dissipation capability of the PCB design
- Improving the thermal coupling of the component to the PCB
- Introducing airflow in the system

Junction-to-ambient thermal resistance is highly application and board-layout dependent. In applications where high maximum power dissipation exists, special care must be paid to thermal dissipation issues in board design. The maximum junction temperature (T_J) of the TPS6130x is 150°C.

The maximum power dissipation is especially critical when the device operates in the linear down mode at high LED current. For single pulse power thermal analysis (e.g., flashlight strobe), the allowable power dissipation for the device is given by [Figure 85](#). These values are derived using the reference design.

PACKAGE SUMMARY

**CHIP SCALE PACKAGE
(TOP VIEW)**

Code:

- YM — Year Month date code
- LLLL — Lot trace code
- S — Assembly site code

CHIP SCALE PACKAGE DIMENSIONS

The TPS6130x device is available in a 20-bump chip scale package (YFF, NanoFree™). The package dimensions are given as:

- D = 2170 ±30 μm
- E = 1928 ±30 μm

REVISION HISTORY

NOTE: Page numbers of current version may differ from previous versions.

Changes from Original (June 2009) to Revision A	Page
• Deleted product preview device number TPS61306 from data sheet header.	1
• Deleted "Product Preview" cross reference from TPS61301 device in Available Options table.	2
• Added "TI" to package marking illustration example	72

Changes from Revision A (September 2010) to Revision B	Page
• Changed I_{STBY} MAX current from 5 μ A to 12 μ A	3

Changes from Revision B (September 2011) to Revision C	Page
• Changed active cell balancing circuitry maximum quiescent current into VOUT from 3.0 to 6.0 μ A	5
• Added additional information related to the dc/dc input current limiting scheme.	41
• Added additional information related to the dc/dc input current limiting scheme.	41
• Added note 2 to REGISTER1 DESCRIPTION (TPS61300, TPS61301) table	54
• Added note 2 to REGISTER1 DESCRIPTION (TPS61305, TPS61306) table	55

Changes from Revision C (August 2012) to Revision D	Page
• Added TPS61305A device in Available Options table.	2
• Added note specifying silicon revision ID bits can differ depending on the product die revision number.	63

DIE-SIZE BALL GRID ARRAY

4207625-9/AJ 09/12

- NOTES:
- A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.
 - B. This drawing is subject to change without notice.
 - C. NanoFree™ package configuration.
 - $\triangle D$ The package size (Dimension D and E) of a particular device is specified in the device Product Data Sheet version of this drawing, in case it cannot be found in the product data sheet please contact a local TI representative.
 - E. Reference Product Data Sheet for array population.
5 x 4 matrix pattern is shown for illustration only.
 - F. This package contains Pb-free balls.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components which meet ISO/TS16949 requirements, mainly for automotive use. Components which have not been so designated are neither designed nor intended for automotive use; and TI will not be responsible for any failure of such components to meet such requirements.
